INDEX TO VOLUME II., 1924.

☞ *Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes, Glycosuria and Sugar, Eye, Ophthalmic, and Vision, Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c., &c., and that regional headings are more frequently used than pathological. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A.) = Annotation, (C.) = Correspondence, (C.M.P.) = Conduct of Medical Practice. (I. and A.) = Inventions and Appliances, (L.A.) = Leading Article, (M.L.) = Medico-legal, (M.T.T.) = Modern Technique in Treatment, (O.) = Obituary, (P.I.) = Parliamentary Intelligence, (R.) = Review, and (R. and A.R.) = Reports and Analytical Records.*

A Concordance of page numbers and dates of Issue will be found at the end of the Index.

A

Abderhalden, Emil (ed.), Handbuch der biologischen Arbeitsmethoden (R.), 175
Abdominal illness in children, acute, diagnosis of (G. Bryan), 737
Aberdeen, S.M.O.'s report, 1148
Abraham, J. Johnston, lectures on gonorrhœa in women and children (R.), 496
Abrams, Albert, 803 ; electronic reactions of (L. A.), 866
Accident prevention, 719
Accidents, psychopathology of (L. A.), 812 ; street, medical attendance in, 360
Acclimatisation in the tropics (A.), 32
Accommodation and refraction, errors of, and their treatment (Ernest Clarke), 5th ed. (R.), 1290
Actinomycosis, case of (A. I. G. McLaughlin and D. S. Page), 114
Addison's anæmia (Robert Campbell oration, Belfast), 1196 ; diagnosis of, by new optical method (Adrianus Pijper), 367 ; (C.), 524

SOCIETIES, MEDICAL.

Aberdeen Medico-Chirurgical Society.—Annual meeting, 1196—Exhibition of cases and specimens, 1070—Tumours of breast, 1035

Assurance Medical Society.—Presidential address, 1047

Brighton and Sussex Medico-Chirurgical Society.—X ray therapy, deep, 1017

Cardiff Medical Society.—Present-day health tendencies in Cardiff, 909

Chelsea Clinical Society.—Dinner, 681

Child-Study Society.—Lecture, 993

Durham University Medical Graduates' Association.—Election of officers, 46

Edinburgh Medico-Chirurgical Society.—Anti-pneumococcal immunity, 1288—Bile-passages, surgery of, 1287—Cataract, senile, intracapsular extraction of, 1125—Exhibition of cases, 173, 1126, 1178, 1288—Meeting, 1036—Ringworm and favus, immunity and sensitisation in, 1125—Visceroptosis, discussion on, 172

Edinburgh Obstetrical Society.—Antenatal, intranatal, and neonatal death, prevention of, 66—Exhibition of cases and specimens, 67

Glasgow Royal Medico-Chirurgical Society, 824

Harveian Society of London.—Clinical meeting, 786—Gift to, 1101—Insurance Act, National, future position of consultants under, 1283—Meeting, 993, 1067

Hunterian Society.—Dinner meeting, discussion on headache, 1285—The medical witness, 1065—Meeting of, 856, 1043

Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded.—Annual meeting, 99

Liverpool Medical Institution.—Arterio-sclerosis and the fundus oculi, 1127—Borderline cases, 1127—Cancer, discussion on, 1340—Empyema, treatment of, 1016—Encephalitis lethargica, 908—Meeting of, 888

London Association of the Medical Women's Federation.—Gonorrhœa, complications of, 1063—Micturition, frequency of, in women, 1339—Meeting of, 859, 1192

London Dermatological Society.—Meeting, 858

Manchester Medical Society.—Backache in women, chronic, 1286—Meeting of, 732

Manchester Pathological Society.—Streptococci in relation to human disease, 1124

Medical Officers of Schools Association, 681, 804, 1043

Medical Society of London.—Encephalitis lethargica, 1015—Gangrene, senile, treatment of, 1122—Insulin in treatment of diabetes, 1234—Lloyd Roberts lecture, 993—Syllabus, 731

Medical Society for Study of Venereal Diseases.—Exhibition of cases and specimens, 1177

Medical Women's International Association.—Forthcoming meeting, 94

Medico-Legal Society.—Dinner, 1313—Hanging as a humane method of execution, 907—Strychnine, fatal dose of, 907

Medico-Psychological Association.—Meeting, 993

National Association for the Prevention of Tuberculosis.—Annual conference, 80

Newport Medical Society.—Meeting, 1124

North of England Obstetrical and Gynæcological Society.—Displacements of uterus, treatment of mobile backward, 964, 1235

Pathological Society of Great Britain and Ireland.—Meeting, 171

Rontgen Society.—Meeting, 888, 1162, 1351

Rontgen Society and Royal Society of Medicine.—Radiology, influence of, on criteria of disease, 119

Royal Academy of Medicine in Ireland.—Carcinoma of rectum, 1126—Corpus luteum, mammalian, 1341—Encephalitis lethargica, sequelæ of, 1180

Royal Medical Society of Edinburgh.—Inaugural address, 931

Royal Society of Medicine.—Anæsthetics in America, 411—Anastomosis of facial and recurrent laryngeal nerves with others, 21—Annual clinical meeting, 117—Annual dinner, 871, 1194—Bakers' eczema, 859—Cancer cells in vitro, 1122—Cancer, increased and diminished resistance to induction of, 1122—Cavernous atrophy, relation of, to glaucoma, 1120—Ciliated epithelium in sinusitis, 20—Congress of Sections of Laryngology and Otology, 20—Cures, universal, ancient and modern, 802—Diathermy for pharyngeal cancer, 20—Ear and throat defects of elementary school-child, 20—Exhibition of cases and specimens, 1122, 1233, 1338—Eye positions, compensatory, 20—Hæmorrhoids, treatment of, by injection, discussion on, 117—Kidney, so-called myelin, 21—Kidneys, polycystic, discussion on, 22—Larynx, chondromata and chondro-osteomata of, 20—Larynx, ecchondrosis of, 20—Meningitis, non-tuberculous, 1281—Naso-pharynx, malignant disease of, 20—Nystagmus, miners', 1120—Pharyngeal cancer, diathermy for, 20—Pharynx, tortuosity of internal carotid in relation to, 20—Pruritus ani, 117—Puerperal sepsis, notification of, 817, 1011—Puerperal septicæmia in cattle, 1176—Rectum, cancer of, discussion on, 117—Rectum, prolapse of, 117—Rhinitis, atrophic, displacement of antro-nasal wall in treatment of, 20—Sacro-iliac disease, 1232—Scarlet fever and measles, otological and rhinological problems in, 21—Social evening, 669—Surgical section, presidential address, 961—Throat and ear defects of elementary school-child, 20—Thyroid gland, diagnosis of malignant disease of, 1231—Tints and their values, 801—Vertigo in relation to otolith and neck reflexes, 20—Vestibular function, experimental basis for theories of, 20

Royal Society of Medicine and Rontgen Society.—Radiology, influence of: on criteria of disease, 119

Royal Society of Tropical Medicine and Hygiene.—Malaria control, 962

Royal Statistical Society.—Meeting, 993

Society of Apothecaries of London.—Dinner to Dominions representatives, 95—Election of Dr. A. D. Brenchley as Master, 458—Pass-lists, 303, 528, 993, 1155

Society for Constructive Birth Control and Racial Progress.—Meeting, 1156

Society of Medical Officers of Health.—Annual dinner, 731—Meeting of, 94

Society of Members of the Royal College of Surgeons of England, 1043

Society for Prevention of Venereal Disease.—Annual meeting, 46; (A.), 74

Society for Study of Inebriety.—Meeting, 777, 857

South African Institute for Medical Research, 1044

Tropical Disease Prevention Association, 198

Tuberculosis Society.—Meeting, 1043, 1313

Ulster Medical Society.—Meeting, 1071

University College Hospital Medical Society.—Opening meeting, 749

West Kent Medico-Chirurgical Society.—Meeting, 993—Purvis oration, 1236

Yorkshire Tuberculosis Society.—Lecture, 772

Sodium morrhuate in the treatment of tuberculosis (John Hume), 162
Somerset, M.O.H.'s report, 1255
Soothill, V. F., injuries about the elbow-joint, 649
Sourds-Muets, les (G. de Parrel and Mme. Georges Lamarque) (R.), 1022
South Shields, M.O.H.'s annual report, 399
South-Western Asylums Research Institute, annual report, 137
Southgate, H. W., case of osteitis fibrosa, 1172
Southport, M.O.H.'s report from, 42
Spanish doctors' visit to London, 147
Spas in transition, the (C.), 884

Addresses to Medical Students.*

I.

LOOKING BACK AND LOOKING FORWARD.

An Address delivered to the Students of St. George's Hospital at the Opening of the Winter Session, Oct. 1st, 1924,

BY SIR ISAMBARD OWEN, D.C.L., M.D., F.R.C.P.,
CONSULTING PHYSICIAN TO THE HOSPITAL; LATE DEPUTY-CHANCELLOR, UNIVERSITY OF WALES; VICE-CHANCELLOR, UNIVERSITY OF BRISTOL.

CIRCUMSTANCES led me at one time to study a rather out-of-the-way chapter of human history: that of the origin and development of Universities in Europe. One of the impressions it left on my mind was that the reputation and success of an academic institution is largely proportional to the degree in which it succeeds in creating a sense of corporate existence among its members, and a corresponding corporate pride; such sentiments implying not only a feeling of fraternity among them, but a sense of their common interest in the credit and reputation of the community as a whole. Where such sentiments prevail—I leave it to psychologists to say why—the effective value of the individual seems to be perceptibly enhanced, to the benefit of himself, of the institution, and of the world at large. There is nothing new in all this. It has long been recognised as the basis on which our much-envied public school system rests.

I was one of those who regretted that so little attention was given to this subject when the reconstruction of the University of London was undertaken in the close of the last century. It was, in fact, the key-note of the counter-scheme that Sir James Kingston Fowler and I put forward at that time. But pray do not imagine that I am about to venture into any University of London questions; I have been wholly innocent of them for many a long day; I would merely express a hope that if any further reconstruction of the University is ever contemplated, the point I have mentioned will not again be overlooked.

[The speaker then made a feeling allusion to the death of Sir Sydney Russell-Wells.]

The atmosphere of London is certainly not one unfavourable to the growth of academic corporate feeling. Quite the contrary, I should say, when opportunity is offered it. I have been brought into contact in my time with many educational institutions in many places, and am free to say that I have never met with a more genuine corporate sense or a stronger corporate pride than among our own particular community of St. George's men. To an old-time St. George's man revisiting his hospital the place cannot but seem strangely familiar at first sight. It is only when he begins to look into details that he will realise what a wholesale change time has made in nearly every appliance which the hospital offers for the comfort and welfare of the sick, the instruction of the student, and the advance of medical science. And one may say much the same of the whole field of medicine and surgery cultivated within its walls. In superficial aspects and habits the physician or surgeon of to-day does not materially differ from his predecessor, but in every detail of his actual work the changes of the last half century have been revolutionary, and not the least of these have come about during the 20 years since I myself quitted medical practice.

MEDICINE A GENERATION AGO.

When I first entered on medical study the teaching of Lister was only just beginning to be followed in England, and at least 95 per cent. of modern surgery was yet unborn. Ovariotomy was a strictly tabooed subject, cerebral surgery undreamed of, and the story of the candidate who suggested removal of a damaged kidney as a possible expedient passed from hand to hand among us as a supreme professional joke. Preventive medicine, too, was in its earliest infancy, pathology still dealt with dead material alone, and no human eye had yet seen a pathological bacillus. The methods of medical education have undergone no less radical changes. It is strange now to reflect that I was a member of the first microscopical class ever held in the University of Cambridge, at any rate in connexion with medical studies. In those days the schools of the London hospitals, which were a gradual development from a system of personal apprenticeship, had only recently completed their organisation by absorbing or replacing the private schools of anatomy and of chemistry that had previously worked in connexion with them. In these later days St. George's has made itself the pioneer of a still further advance in the organisation of medical education, in deciding to relinquish the teaching of the preliminary sciences to the University of London, to which it properly belongs, and to confine itself to its legitimate fields of pathology, public health, and clinical medicine and surgery. The change was made, I fear, at some sacrifice of immediate interests; but it was a step in the right direction, taken in accordance with the accepted academic policy of the time, and sooner or later the example will tell elsewhere.

The term "clinical," in medicine as well as in surgery, conveys a somewhat different implication to-day from that which it did a generation ago. To a man who, like myself, has been little engaged in medicine the last 20 years, nothing is more striking than the degree to which laboratory methods and laboratory science have now come to supplement, or even to supplant, older methods of clinical investigation, whether for purposes of research or in the daily work of diagnosis. Many a clinical problem of a kind which in older days we used long and anxiously to puzzle over at the bedside is now settled promptly and decisively by a reference to the laboratory, and the laboratory has become as essential an appendage to a clinique as a dispensary.

Meanwhile it may be well to recall that the work of the laboratory is not the only aspect of the search after truth to which the inspiring name of "Science" applies; and to remember that clinical observations in the older sense of the term, provided that they are accurately made, and conclusions drawn from them, if logically drawn, are every whit as "scientific" as the work of the chemist and the physiologist, demanding to the full as great powers of mind successfully to deal with them. There may still remain a great part in the advancement of medical science for the older methods of investigation to play.

THERAPEUTIC SCIENCE.

This is certainly the case with one branch of medical research which has somewhat lagged behind the rest, and towards which in the nature of things the laboratory can contribute only incidental aid; I mean therapeutics. I am not seeking to question the value of the light that pharmacology has thrown on the mode of action of remedies, or ignoring the many recent discoveries of new and promising medicinal agents; but behind all this there still seems (if I may venture to say so) to be the old lack of a real science of therapeutics; of machinery for accurately determining the power, if any it have, of a reputed remedy to counteract a particular disease, or for a comparison of the value of one remedy with that of another. These might seem to the uninitiated simple determinations to make; in reality we know them to be quite the reverse. Our forefathers' therapeutic reasoning was simple enough. It rested on an unformulated but practically accepted assumption that the natural course of a malady was towards an unfavourable issue unless checked by artificial means. Granted this major premise, it logically resulted that any improvement observed in a case of illness could be confidently credited to the treatment employed at the time. A certain *vis medicatrix naturæ* was admitted in theory, but in practice ignored. This manner of regarding therapeutic questions, I need hardly say, still prevails largely among the public, and is, in fact, the basis on which the whole fabric of quackery is built. There were always some sceptics among us; one of the ablest physicians of my younger days, the late Sir William Gull, used to assert a diametrically opposite position. The natural tendency of the majority of maladies brought to a physician's notice, he urged, given due shelter, rest, and diet, was sooner or later (a rather variable later) towards recovery; and the participation of a remedy in bringing about the favourable results was at best a doubtful proposition. In an earlier generation a similar view appears to have been held, though hardly preached, by a still greater man from among ourselves—Thomas Young, the physicist.

---

* With the consent of the authors all these introductory addresses are reproduced in somewhat abridged form.

Modern medicine, mindful of its grave responsibilities, does its best to steer a judicious middle course between undue scepticism on the one hand and undue credulity on the other; but the standing need, it feels, is to have such a course effectively surveyed and sounded, and definitely marked on the chart. The method of accomplishing this is in principle sufficiently simple, but on the other hand exceedingly difficult in application.

COÖRDINATED CLINICAL OBSERVATION.

It is when the practical application of the principles of therapeutic science begins that the difficulties surrounding it present themselves; for the therapeutic inquirer in all but a limited number of instances finds himself presently confronted with an indefinite series of variations in the very subject-matter of his inquiry; variations in the course, the duration, the severity, and the particular manifestations of cases, even of whole epidemics, of the same malady, to say nothing of variations in the constitution of patients and in their individual susceptibility, whether to disease or to remedy; variations so manifold as to require a widely extended field of observation to eliminate their effects, such a field as is seldom available in the practice of a single observer. A less obvious but no less real difficulty lies in the fact that clinical observation for the purpose of therapeutic inquiry is an art which in itself needs a certain special training if results of real scientific value are to be obtained. Considering all things, small wonder that so little has hitherto been accomplished in the direction I am speaking of, and that practical therapeutics in consequence is still so largely at the mercy of uncertain, conflicting, or even mutually contradictory individual views. Small wonder, too, that the establishment of a real science of therapeutics based on exact statistical methods has been so often in the past pronounced an impossibility. Is it really so?

I take heart of grace to propound the question afresh, because the three hardest-worked years of my life at St. George's were spent in an endeavour to prove the possibility of such a thing; with the result of convincing at least myself that there was no impossibility in the matter, granted three conditions—that is, a sufficiently wide field of inquiry, unity of aim and method among its cultivators, and (possibly hardest of all to obtain) adequate means to retain the services of a staff of fully trained observers, working under a single direction. With the growth of the scientific spirit another new spirit has entered the medical world—the spirit of coöperation in scientific research. In the growth of that spirit, perhaps, one may look for the future hope of therapeutic science, and anticipate that what was deemed Utopian in 1880 may, as many other things have done, become an admitted possibility of a more modern time.

II.

SOME PREVENTIVE ASPECTS OF MEDICINE.

Introductory Address on the Occasion of the Opening of the Session at the Middlesex Hospital on Oct. 1st,

BY CHARLES PORTER, M.D., B.SC.,
MEDICAL OFFICER OF HEALTH, ST. MARYLEBONE.

THE Dean, to whom I owe the invitation to act as lecturer to-day, very kindly also chose the subject upon which I was to speak. "You will," he said, "deliver a lecture on Some Aspects of Preventive Medicine," but I propose to alter his title, making it read Some Preventive Aspects of Medicine. This I do with one object only, to save the men who are just beginning the study of medicine the trouble of finding out for themselves or the pain of learning from a non-medical source that medicine is not all curative in its aim but has a preventive aspect as well, and further, they must learn and better thus early that preventive medicine as it is now coming to be understood is not exclusively a matter for specialists but for every man and woman entering upon the practice of medicine. Largely I desired to speak thus early because of a feeling I have that once you get into the wards and begin to traffic with disease, to see it and study it and the multitudinous methods adopted with a view to alleviating it, you may come to regard it as inevitable, to believe that it is absolutely true that "man is born to trouble as the sparks fly upward" and to consider the saying "Prevention is better than cure," a saying only, so far at any rate as sickness is concerned.

It is so easy to come to these conclusions; the system of medical education now in vogue almost drives the student to them. He sees so much of disease, and the various conditions are so beautifully catalogued for him that it is not to be wondered at that he comes to regard diseases and disease groups as established things and to continue to so accept them throughout his professional life. Also he sees and hears and reads so much of treatment of disease and the success that attends it that it is not surprising if, in regarding sickness and suffering, he should think immediately and exclusively of means and methods of alleviation. That he should end up by disregarding the prevention better than cure statement or entirely disbelieving it is not surprising either. Curative medicine he can see; it works; he sees it at work and he sees the results obtained. Prevention and preventive medicine: are they anything more than conceptions? If not, where are they, where do they work, what do they do, what have they done? If they have done anything why is the out-patient department always thronged, why are the wards always full, and why does the secretary-superintendent eternally dream of millionaires and hospital extensions? These are reasonable and pertinent questions—questions I should like to think the medical student occasionally asks, since to me it would be evidence that he recognised the existence of a preventive aspect to medicine and gave some thought to the question of prevention.

THE ACHIEVEMENTS OF PREVENTION.

If he has doubts, and I admit he has reason for them, I should like to explain that so young is preventive medicine that practically there has been nothing more done than a mere clearing of the ground; but in connexion with even these preliminary efforts it is possible to show results. These are in the form of reductions in the number of persons dying annually, reductions in the number of cases of some diseases, and the almost complete disappearance of others, and associated with these happenings such benefits for the people as lessened suffering, worry, and anxiety, a prolongation of life with better health, and more comfort to enjoy it with.

The story of these gains is unfortunately told in figures, and most people hate figures so much that I hesitate to mention them, but perhaps I may be forgiven for giving only a few. Let the first of these relate to the period round about 1875, when it may be taken interest in preventive medicine began to awake, since it was in this year the legislature demanded that works in relation to public health should be organised and a special preventive medical service created. On an average between 1875 or a little earlier and 1880 the annual number of deaths was 517,831, the average number of people alive being 24,255,271. This gave a death-rate of 21·4 per 1000. In 1923, the organisation having fairly well established itself and views as to the qualifications of the preventive medicine specialists having become crystallised as evidenced by the introduction of new regulations as to training and examination, the number of deaths had fallen by something like 100,000, and the death-rate to 11·6, just over half of the previous average rate. These things had happened, it may be noted, despite the fact that the population had increased by no less than 14,000,000 to 38,403,000. Why was there all this reduction ?

Something must have happened to disease ; something that may for convenience be called "prevention" must have been exerting influence on it. Amongst the infectious diseases particularly the contribution has been extraordinary. Take scarlet fever, which in the period between 1871–80 added on an average each year over 17,000, killing 7 out of every 10,000, and in 1923 less than 1000, or about 1 per 50,000. Take small-pox, which contributed 7 to the total number of deaths in 1923, as compared with an average of nearly 6000 in each of the ten years 1871–80. Typhus fever which added regularly round about 1500, scored 1 in 1923, and enteric fever, which, as I have already indicated, is getting into the group of disappearing diseases, as against an average of nearly 8000 put on only 450. Even diseases that we regard as prevalent have yielded to the efforts that have been made, lung tuberculosis—consumption—contributing yearly not over 50,000 but a rough 30,000.

In the case of other forms of consumption there is an equal, if not a greater, improvement, though, since the fall is only from 18,000 to 8000, we have not yet reached the state I have been assured exists in Boston, U.S.A., where cases of surgical tuberculosis affecting bones, joints, &c., are practically never seen in hospital practice. Though we have not yet reached that happy condition we are surely approaching it. With 10,000 fewer deaths there must be a marked reduction in the number of cases, a reduction that will become even greater as the improvement in the milk-supply, for which all interested in preventive medicine are working and hoping, is brought about. If there has been reduction in the number of cases of, as well as of deaths from, tuberculosis, and you may take it there has been and is a progressive reduction, so also there must be fewer cases of the other diseases in which there has been a falling off in the number of deaths, and if there are fewer cases there must be these other things I have claimed should be credited to preventive medicine—lessened suffering, lessened anxiety, and increased healthiness.

In the case of certain other diseases the conquest is less complete, and it is not possible to claim more perhaps than that they have been fought to the point of yielding or even only to a standstill. At the moment one of the most important in this group is diphtheria, the number of deaths from which in 1923 was 2722, only very little lower than the average for 1871–80—viz., 2943. Even in regard to this, however, some claims may be made—viz., that it is less dreadful than formerly, and is even threatened with extinction, since it is now possible by means of tests to discover whether or not an individual is liable to attack, and if he proves to be so to afford him protection by something in the nature of vaccination.

The results that have been obtained in the United States particularly, but also here and in certain continental countries, by this procedure appear to justify the belief that in it there exists a means of increasing the amount of control over this disease. In America—a land where the readiness to investigate is very marked and money to encourage it easily obtainable—investigations are now proceeding on similar lines in the case of scarlet fever. As this disease is one quite difficult to control any addition to the means of dealing with it will be very welcome.

The last fact in relation to the reduction in the number of deaths that has occurred in the years since 1875 I propose to mention is this: that it has been most marked in the earliest period of life. It is the babies who have benefited most, who have been given year by year not only an improved chance of life but a higher chance of health. Between 1871 and 1880 so small was the chance that on an average out of every 1000 born 150 died within 12 months. In 1923 the extent to which the chances had improved is shown by the fact that the rate of mortality had dropped to 69 per 1000 births. To me this falling rate of mortality amongst infants always seems the most wonderful thing ; much more wonderful than the effect produced on the diseases I have mentioned, more wonderful even than the increased expectation of life—about 20 years—given to this generation. More wonderful because it has been obtained as a result of the operation of purely preventive measures ; more wonderful and more encouraging because it shows what preventive measures can do.

THE DOCTOR AS TEACHER.

Largely the baby lives have been saved by dispelling ignorance ; by teaching the methods to be adopted in relation to the care of life and health ; by encouraging the practice of these methods, seeing they are practised and demonstrating the effects of their practice.

It is not only in regard to the care of infant life and health that there is need for dispelling ignorance. It is not only in infancy that benefit is to be derived from the appreciation of right methods. Doctoring, you must learn, does not mean merely the treating and curing of ills, and the service is not to the sick alone. The title "doctor" you hope to gain gives you the right and ability to teach. It imposes on you the duty of teaching, and you *will* teach. Indeed, you *must* teach. More and more definitely there is evidence of a demand from the people that they shall be taught. They desire to know how to safeguard their life and health. They, if not you, have studied the figures, some of which I have quoted, and have noted the decreases and the disappearance of disease and have heard the claims and promises of the preventive medicine experts and the health authorities. They accept that much suffering is avoidable and they are insisting that they shall be told how to avoid it and how to live as the Bible says they should, to three score years and ten. They believe that the medical profession knows and that the secret is imparted to medical students in medical schools.

THE PREVENTIVE ASPECT OF PANEL PRACTICE.

The law of the land, in fact, promises them prevention and provides for its application. That, at any rate, is what the National Health Insurance Acts seem to me to do, and every medical practitioner who becomes a panel doctor and accepts service under the Acts undertakes to carry out preventive as well as other duties. He is, as the chief medical officer of the Ministry of Health has said, a "missionary of health." It is extraordinary how the views with regard to the Insurance Act have changed, and how many doctors as well as patients who formerly could see no good in it are coming to regard it as a measure of definite value.

To many practitioners, it may be, its value as a preventive measure may not be apparent as yet, but they will come to recognise it. There are too many people referring to it as such ; too many people quoting statistics showing how many thousands of years of work are lost per annum and how many might be saved if the medical services provided for by the Act were properly made use of. Also, as I have already said, there are the people who are demanding that the necessity for suffering shall be removed and that the

Act shall be operated to this end. They will no doubt see that it is operated and that efforts are made in the direction of real prevention. These efforts, however, will not properly be made and real success will not be attained until they recognise further that they themselves have some responsibility in regard to prevention. It is not a matter for the doctor, the teacher alone, as they suppose. The least of the difficulties, I have said, was the finding of the teacher. The greatest difficulty is those who have to be taught. There must be the will to learn, to coöperate; the desire to accept the teaching and apply it. There must be submission to supervision, perhaps not so close as is the case in infancy, but still sufficiently close. If the two groups, the doctor and the people, will realise their responsibilities and will coöperate for prevention, prevention will follow and results perhaps not so wonderful as those that have been obtained in the case of childhood but still wonderful will be obtained.

The Study of Health.

At the moment and in my capacity as a member of the staff of the Middlesex School—a position I am immensely proud to occupy—it is with the budding doctor I am chiefly concerned.

That concern is to beg of him not to devote all his time, energy, and enthusiasm to the observation of the diseased and the study of disease. There is much to learn of the healthy and of healthiness, and it is going to be worth while learning it. An American professor of preventive medicine has recently caused a certain amount of amusement by suggesting that, well or ill, everybody should undergo a complete medical examination at regular intervals. By the age of 60, in his opinion, everybody should have been thus completely overhauled at least 75 times. The reason for the amusement is not clear to me. It is largely because I feel so certain that the benefit of regular and frequent medical inspection will soon be widely recognised, and that the medical profession will come to favour and recommend it, that I advise the turning of attention to the study of the healthy, of health and the maintenance, the treatment of health.

That the profession should recommend such examinations is not in the least unreasonable. Since the time when it became fashionable to regard the teeth as the source of the bulk of our ills we have been preaching that everybody should visit the dentist once or twice a year. The teeth are not, however, the only organs in the body that may, though there is very little evidence of the fact, be the seat of some trouble that can be readily stopped if recognised early and promptly dealt with. Some day, perhaps, the profession will think it worth while pointing this out and make the obvious recommendation; or perhaps, happy thought, the dentist may return the doctor's compliment and point out the necessity for a wider overhaul than he can give.

Medical Inspection.

A further reason that might be offered for failure to see humour in our professor's suggestion is that amongst quite a large section of the population of this country the practice of medical inspection has already been established. Of the hundreds of thousands of children attending the elementary schools quite a respectable number before they leave school must have had a considerable proportion of the 75 medical inspections due to them, having undergone examination at the child welfare centres in babyhood in addition to the three or four to which they must submit during the period of school attendance. The unfortunate thing is that these inspections cease on leaving school and that the only class of the population to receive the advantage is that privileged to attend the elementary schools. That benefits spring from these inspections there is abundance of evidence, but they should not be limited to any age or class.

Having been begun, however, the practice is certain to spread, and the medical profession must be prepared to encourage the spread and to carry out the work that will be involved.

III.

REASONS FOR ENTERING THE MEDICAL PROFESSION.

Delivered on Oct. 1st to the Students of Charing Cross Hospital on the Occasion of the Prize Distribution at the Opening of the Winter Session,

By Sir HUMPHRY ROLLESTON, Bt., K.C.B., M.D.,
PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

After the privilege of congratulating the prize-winners it is natural to turn to those who have not on this occasion gained the palm, though they have honestly struggled in the dust of the arena, and to remind them that there are after all possible advantages in their lot; just as hereditary wealth or a distinguished parentage is often a handicap by involving the absence of the keen spur of poverty or by providing a false sense of a private and easy road to eminence, so may early success induce slackness. So widespread is sympathy, born of similar experience, for the unsuccessful that there has perhaps been a tendency to minimise the influence of prize-winning by pointing to Senior Wranglers who have not been heard of again, and by drawing attention to the early failures of men afterwards famous. Although precocity may be short-lived and overwork may induce sterility, it seems to remain true, as Sir Squire Sprigge concludes in "Physic and Fiction," that the prize medical students on an average continue to do well. On the other hand, everyone does not develop at the same rate, and the student who matures slowly may eventually be mentally stronger than the more brilliant contemporary of his hospital days. What we are pleased to call chance, because the responsible factors are hidden from our eyes, plays an enormous part in our future, and all we can do is to work so as to deserve success. There is, indeed, an advantage in competing for prizes quite apart from the place obtained in the list; it is a preliminary canter and part of the training for the compulsory examinations that await the student at another place. It provides practice in clear expression and marshalling of knowledge in the written paper, and accustoms the candidate to the trial of a viva voce examination when a question on an all unexpected subject suddenly impinges on an anxiously strained brain and demands an accurate answer. There is thus a serious reason for congratulating those who "also ran" on having carried out this part of their training, not only for the caudine forks of an examination, but for the emergencies that will from time to time crop up in professional life long after the fitful fever of examinations has been well-nigh forgotten.

Let me on behalf of the staff of the Medical School and Hospital extend a hearty welcome to those who are now joining this medical school; it would be impossible to give them better advice than to follow the example and traditions of the great men, such as T. Wharton-Jones, T. H. Huxley, T. H. Green, and F. W. Mott, who have adorned this famous institution.

The Call of Medicine.

Although you have all committed yourselves to the profession of medicine it is not a mere act of curiosity to mention the reasons that may lead up to such a decision. The reasons attracting men and women to our profession may decide in advance what form of practice or activity they will ultimately adopt, and to these brief reference will be made, but usually the wise advice not to specialise early has been unconsciously followed.

The Bread-and-Butter Aspect.

While one, and certainly the commonest, object of entering a profession is, of course, to gain the wherewithal to live, this can be much more easily and successfully attained by going in for business or trade, strictly so called, than for medicine, which has been described as a noble profession but a decidedly bad trade. Still undoubtedly many choose medicine with this aim in view, for, at any rate in the past, more members of the healing art gained a living of a sort than is the case among the followers of the Church or the law; it is true that the prizes are few, and the income is often small, sometimes, indeed, barely a living wage, or, as it has been called, a "starveling"; before the war it was, I believe, estimated that the average income of the members of the profession as a whole was about £300 a year, though this must have been hard to arrive at and then approximate only. Now with the rise in the cost of living it must be much higher, possibly £500 to £600 a year. But just at the present moment there is considerable reason to believe that the medical profession is overstocked by those recently qualified; last year the number of new practitioners registered was 2482, the highest on record; and the number of medical men is increasing more rapidly than the population, so that the rate is approaching one medical man to 1000 of the population. As the result of the rush into the profession after the war, the Universities and examining boards are now at the crest of the wave as regards candidates for the final examination—for example, at the Final Conjoint Board examination in July last there were more than 500 candidates up; it is true that they did not all get through, but that the recently qualified are finding it hard to obtain resident posts there is, I fear, no doubt. This temporary condition must of necessity right itself in accordance with the laws of demand and supply, and indeed this corrective process may have begun already. Last year the entry into the medical profession dropped from 2000 in the two previous years, and 3500 in 1919, to 545, which is little more than a third of that (1500) in the first year of the century. There is also a very considerable fall in the entry of women into the profession; whatever the cause, there is no question that 1923 saw a very distinct drop, which contrasts with the war and post-war rise in the number of female medical students. The evidence of overcrowding among the qualified women and realisation of the difficulty of obtaining posts when a degree or diploma has been obtained may have warned parents not to encourage their offspring, especially their daughters, to choose our profession.

Heredity and Environment.

A not uncommon reason for entering our profession is the accident, so to speak, of environment or heredity. When the father is a medical man the home atmosphere often prepares the son to follow in the paternal footsteps as a normal course of evolution, especially as there may be a practice waiting for him; so without any special ambition or inclination for another walk of life he regards it as a natural family succession. I know of a family with seven generations in succession. This is perhaps a survival or an unconscious imitation of ancient custom, for in very remote times the art of healing was hereditary from generation to generation in the sacerdotal caste. In Ireland until a comparatively recent period the profession of physic passed from father to son, just as did the practice of other arts and crafts, and was a relic of the time when a medical practitioner was attached to the clan or house of a chieftain (Kirkpatrick). On the other hand, a boy or girl may early decide on the physic line and keep to this resolution; the impulse may date from some accidental experience, such as injury or illness, and the resulting contact with the striking personality of a medical attendant; Sir William Bowman is said to have been led to take this step by his interest in the treatment of a wound in his hand sustained when experimenting with gunpowder. Sydenham was attracted to the profession he so greatly adorned by the influence of Dr. Thomas Coxe who was attending his brother, Colonel William Sydenham, in 1646. An allied but apparently curiously infrequent reason is the desire to be in a position to look after one's own disabilities. Elisha Kent Kane (1820–57), surgeon in the United States Navy, who went on the two American expeditions (1850–51, 1853–55) financed by Henry Grinnell in search of Sir John Franklin, originally intended to be a civil engineer, but after an attack of rheumatic endocarditis he was advised by his friends to take up medicine on the ground that he would be happier if he understood and so could manage his own case. Interest may suddenly be awakened by the accident of reading a medical book or article, as in the case of Dr. Tertius Lydgate in George Eliot's "Middlemarch" (p. 104), a portrait known to have been drawn, in part at least, from life. Among those who, like William Hunter, the elder brother of the more famous John, have started life with the intention of entering the Church, but have abandoned that calling for the cure of our vile bodies, was Sir William Osler, who is believed to have been partly influenced in taking this step by reading Sir Thomas Browne's "Religio Medici."

EDUCATIVE VALUE OF MEDICAL STUDY.

A few men, paradoxical as it may at first sight appear, take a medical degree without any intention of ever practising; this is not, as sometimes happens in the case of the Bar, from a belief that it is a kind of social distinction to belong to a learned profession, but because they have already decided on devoting their lives to investigation or teaching in one of the sciences, such as physiology, biology, biochemistry, morphology, or pathology, which are so closely bound up with medicine. Such men rightly recognise that their outlook is greatly broadened by passing through the whole of the medical curriculum, that as research workers they are better placed to understand the bearing of the problems to be solved, and that as teachers of medical students they are thus in a much more advantageous position to deal sympathetically and for the best with future practitioners. In short, the experience gained by passing through the medical curriculum tends to alter the outlook of the teacher of the preliminary biological sciences. Let us contrast the extremes of the groups of teachers—those who know their science only with those who in addition have been through the curriculum—and think for a moment of the difference in the attitude that may be adopted by the two categories of teachers; no doubt much could be said for both; a teacher of the first group might say in his enthusiasm that his function is to teach and examine on the science, whereas one of the other class would consider that his business is to ground future medical men in what he conceives to be necessary to ensure their efficiency.

STIMULANTS AND ANODYNES.

In the days that were earlier, men sometimes entered the medical profession because of their ambition to be in one of the fighting forces; for when prevented by mental or bodily defect from gaining admission to the executive branch they fell back on the Royal Naval Medical Service, the Royal Army Medical Corps, or the Colonial Service. Love of travel and of adventure, which can be gratified in the Services, is another possible incentive, and there is in addition the material attraction of a pension to fall back on. But the shortage of entries into the Services at the present time shows that these factors are no longer operative. Similarly, the number of medical men who now enter the mission field is so small that a desire to be a medical missionary accounts for very few entries into our profession. But how many take up medical work from feelings of real devotion to their fellows, and quietly carry through this ideal in the ordinary rough and tumble of life, it is impossible to guess.

A somewhat unusual reason, for at any rate there are few such confessions, for adopting the medical, though it is far from unknown in the nursing, profession is disappointment in love. James Macartney,[1] the distinguished professor of anatomy and chirurgery at Trinity College, Dublin (1813–37), when refused by Miss Mary Ekenhead, "determined to adopt the profession of surgeon in order to harden his heart"; but the course of his love affairs soon turned into smooth waters, and after marrying Miss Mary he became a demonstrator of anatomy to Abernethy.

Paths in the Medical Field.

The factors responsible for taking up medicine may determine the line of practice, general, consultant, specialist, or in the several services of the State, that is eventually adopted. Heredity in the form of a family practice is an obvious example of a reason for becoming a general practitioner; early marriage and the need of money, or love of country life may have the same effect. A bent for research and seeking out "the secrets of nature by way of experiment" of course provides whole-time pathologists, physiologists, and biochemists. Ambition backed by a certain degree of ability and patience of no small degree is responsible for most of those who attempt consulting practice; but even when the decision has been made so far the choice of medicine, surgery, or obstetrics and gynæcology may be determined by opportunity or accident—i.e., the contemporary prospects in these departments of practice at the medical school to which the individual is attached. Thus at one hospital two men who started as general physicians and another who was well known as a pathologist eventually became gynæcologists, and careful calculation as to probable vacancies has been known to settle the choice between medicine and surgery. Interest and technical skill are the natural reasons for adopting one of the special branches, such as ophthalmology, laryngology, otology, orthopædics, urology, anæsthetics, or dermatology, and there is the mundane advantage that the wait during what has been called the mere bread stage, before butter, much less jam, can be afforded from the rewards, is not so prolonged as in the case of the general consulting physician.

IV.

THE MEDICAL MAN OF THE FUTURE.

Delivered to the Students of Westminster Hospital on the Opening of the Winter Session, Oct. 2nd,

By H. J. WARING, M.S., F.R.C.S.,
DEAN OF THE FACULTY OF MEDICINE, UNIVERSITY OF LONDON;
VICE-PRESIDENT, ROYAL COLLEGE OF SURGEONS
OF ENGLAND, ETC.

It is perhaps not altogether unprofitable at times to turn from the record of what has been or a description of what is, to a guess or a surmise of what may be. It has certain advantages, too, over the processes of recording the past; it does not call for the same stern and rigid adherence to fact; it leaves more scope for the imagination: it is a game in which all can join; and you cannot be proved to be wrong—at any rate during your life-time—and the corroboration or otherwise of your prophecies subsequently is a matter which does not very greatly concern you now. I propose, with your concurrence, to give my imagination its head and to make you a present, which I hope may not be wholly unacceptable, of some speculations regarding the medical man of the future. They are speculations for which I do not claim any special powers or authority; they are merely the extension and modification in the imagination of some of the processes and tendencies which I have observed actually at work to-day in the realm of medicine.

The Youth of Medical Science.

Now medicine as a *science* is still very young, although as an art—a profession—it is one of the oldest. If we contrast mathematics and medicine we realise the difference. Greek thought in the world of mathematics is one of the wonders as well as one of the glories of the human mind; imagination, rigorous proof, logical demonstration—all these qualities are present in their excellence. But Greek thought in the world of medicine was of another order. It is true that we find some of the qualities which we still look for in the good physician: we find, for instance, keen and reflective observation; we find a high standard of professional rectitude, and so on. But we cannot say much more than that careful empiricism was the main guide; it was certainly the safer guide. Of anatomy practically little was known and no wonder, when dissection was profanation; of physiology little more, and that erroneous; and such surgery as was practised seems, as far as we can see, to have inflicted the maximum amount of suffering on the unfortunate patient. We are told, at any rate, that the vigour of his protest was proof of the efficiency of the treatment. There is in fact in direct contrast to mathematical thought little of the heritage of Greek thought of value to medicine, and the great name of Aristotle, the prince of observers, was positively a hindrance when in the sixteenth and seventeenth centuries the science of medicine was born, and medicine made a fresh start, based on the anatomy of the great continental teachers, and not less to the labours of our own William Harvey. This is not the only English name. John Hunter, Cheselden, Jenner, and, of course, Lister—names like these stand out and there are hosts of others—less famous perhaps—but men who were sound clinicians and observers, good medical men and possessed of an abundance of those qualities which were necessary to maintain the contact which in medicine is at all times needed between science and human life, that empirical skill, that sanity and common-sense and humanity which, when the *Science* of Medicine was in its very infancy, encouraged it and fostered it and gradually made it what it is to-day.

Science and Practice.

The *Science* of Medicine, though growing vigorously, is still very young, and the probable manner and direction of its growth in the next few years are matters which seem to me to have a great interest for those of us engaged in different ways in the practice of medicine, and especially to those of us who are occupied with questions of medical education. I consider the present time to be a critical one in the development of science and practice. Think, for example, of the great strides made in recent years in chemistry and physics in their application to living organisms and of the resulting sciences, biochemistry and biophysics, which have wrought changes which one may almost call a revolution. I think that the next few years will see further great and important changes. I may not see them myself, but some of you here to-day may do so; and whether I am right or whether I am wrong in my judgment of the particular manner and direction in which those changes will manifest themselves, I think there is no harm and there is probably some good in letting our minds play about with ideas as to possible future developments, and to maintain towards them a certain suppleness and alertness of mind. Criticism—yes—and dissent if you like, but not apathy or indifference—you—all of us—are not old enough for that. I hope we never shall be!

Specialisation and Its Dangers.

You cannot have failed to notice two great processes at work in medical investigation and treatment to-day. They are distinct, though in some respects they are related, and they have both been operative for some years, although the last few years have seen a pronounced extension of their activities. The first is the process of specialisation. The historic division of function between physician and surgeon has given place to countless subdivisions among both branches of the profession. The portions of the human frame and its various organs have been allotted to, or appropriated by, the specialist, whose business it is to be especially conversant with some small territory, and who often boasts of his ignorance of what is outside his boundaries. The eye, the nose, the ear, the throat, each has its special guardian;

it is true that sometimes two or three of these may be found associated, but this is, I feel sure, only a transient phase—only recently the University of London, with the assistance of a generous benefactor, has founded a lectureship in otology. And these are only illustrations. The heart, the chest, tuberculosis, venereal disease, diseases of women and children, the wrongly-named orthopædic surgery —I need not go on to particularise. Doubtless you have heard of specialists in the vermiform appendix. Then, in addition there are what I may call specialists in investigation, pathologists, bacteriologists, biochemists and biophysicists, including, of course, investigators into such subjects as X ray and electrical treatment. This extension of specialisation is, I think, to a great extent inevitable, and up to a point it is, I think, a welcome and desirable process. It is only by means of specialisation that it is possible to make those additions to our knowledge which we call progress, and it is the specialist who can extend the frontiers of our knowledge. But the process has its dangers. One of them is this. The specialist tends to work in isolation and is concentrating all his activities on the one particular branch which he has made his own. Unless he can work in direct relation with other members of his profession this concentration may degenerate into an obsession and he will view every problem from his own particular angle. Further, specialisation is bringing about some unexpected repercussions in medical education, and those who like myself are particularly concerned with medical education at the University, the General Medical Council, and elsewhere, are being constantly met with new demands and new problems. The specialists, who naturally hold that there is nothing like leather, are claimants for the inclusion or recognition of their subject in the curriculum of the medical student. But the student, and this you know full well, replies that life is short, and that even with the lengthened curriculum, the inclusion of all the specialties is a physical impossibility. He is right too; and under the present system there is not time for more than the inculcation of the fundamentals of medical education—a thorough grounding in the preliminary sciences, the intelligent utilisation of the organs of sense, and the acquisition of sound *principles* of medicine and surgery.

NEW METHODS.

The second outstanding feature in modern medicine is the recognition of fresh curative and ameliorative agencies and their continually extended employment. The sweet simplicity of faith which held that the contents of a bottle poured down the throat was the best and in some cases the only method of effecting a cure is now a thing of the past—except perhaps in the ingenious advertisements of patent-medicine vendors. Recently it has taken another form, and we have such irregular practitioners as the napropath who claims to cure all the ills of man by a varied stimulation of the nape of the neck—correctly applied; but these are passing vanities. The human organism, it is agreed, is far too complicated a mechanism to be corrected and adjusted by such simple methods. It is indeed only in comparatively recent years that we have learned how complicated it really is. The physiologists announce every year some further mapping of hitherto unknown territory; the pharmacologist has some new biological reaction to report. But these are by no means the only explorers. Other sciences are taking possession. The study of biochemistry and biophysics is leading to fresh knowledge and fresh treatment, and electricity and radium and light and heat are all being pressed into the beneficial service of diagnosis and of healing. Gradually the forces of all the sciences are being focused on the great task of curing or relieving suffering humanity.

The full significance of this development at which I have only glanced has yet to be appreciated. It is destined, I believe, to revolutionise the practice of medicine and surgery. It has this much in common with the growth of specialisation, that it makes increasing demands upon the time and work of medical students, but it is a different kind of demand. It is not merely a question of a particular method of treatment or of profound acquaintance with some branch of disease; it is more than that. It is a question of new methods of approaching the whole phenomena of human life, of evaluating the human body in terms of physics and chemistry, or if that is putting the claim too highly, it is at least making it necessary to emphasise more strongly than ever the importance of the so-called preliminary or fundamental sciences in medical education. There is, I know, a universal feeling among medical students that the time spent on the study of chemistry, physics, physiology, and pharmacology, and so on, is largely a waste; that these things are regrettable incidents in a student's career, and until he has done with them and has "got into the wards" his medical education has not really begun. I understand this impatience and the desire to get, as it were, to closer grips with the actual practice of medicine, but while I understand, even while I sympathise, I cannot say that this is right. I am afraid it will be little consolation to some of you when I say that in my opinion the medical student of the future will have to spend more and not less time on the fundamental sciences; that in fact to a much greater extent than to-day the value of his work in the wards will be in direct proportion to the preliminary scientific work prior to admission to the wards.

THE FUTURE OF MEDICINE.

Now I want to turn to this question: What is going to be the cumulative effect of these two great developments, the increase of specialisation on the one hand, and the constantly increasing employment of new diagnostic or curative agencies on the other? The answer to this question is really the prognosis of the future of medicine. You will already have observed this fact, which I think is not controvertible —namely, that a patient in a large general hospital, the poor patient as well as the paying patient, has open to him larger, better facilities and resources than any patient outside—no matter how rich or well-to-do he may be. All the tremendous resources of a modern hospital, its laboratories, its elaborate instruments, its trained staff of physician, surgeon, specialist, its pathologist, radiographers, and so on, can be and are employed first in tracking down and discovering the disease and then in its eradication and cure. The recognition of this fact is not confined to medical men. The lay public have in recent years become increasingly aware of it, and instead of the reluctance to enter a hospital—a survival it may be of the pre-Listerian day—the upper- and middle-class public who would formerly have been treated at their homes show a willingness, almost an eagerness, to enter a hospital, and the provision of adequate accommodation for paying patients is now one of the problems which confront the governing bodies of hospitals in London and the provinces. This tendency, as I have said, is growing, and its continued growth is, I think, inevitable, as inevitable as the division of labour in industrial processes, and for similar though far more potent reasons. The investigation and treatment of disease require modern buildings and plant specially adapted for the purpose, and a highly-trained personnel such as one would find in any modern successful factory. No one would now expect any one man to be so conversant with every part of a motor-car as to be able to repair it; we know by sad experience that if any serious trouble develops the part involved has to be returned to the maker for expert and specialised treatment. What, then, are we to expect of the human body, which is infinitely more complicated, delicate, and subtle than any motor-car? Is it reasonable to expect any medical practitioner, however learned and experienced, to be able to give in a complicated case anything more than a general, a tentative diagnosis, to act so to speak as a "sorter" and to refer a patient to the appropriate expert. And even if the seat of the trouble is correctly located—and let us concede that the powers of an accomplished physician do not stand in need of the help of the elaborate laboratory apparatus which a hospital provides—how in many cases is the appropriate treatment to be given without the help and coöperation of others? We know, of course, that in various ways that necessary coöperation and assistance is obtained, but it is done very often circuitously and indirectly. To my mind, however, this is not enough, and I envisage an organisation of the medical profession in which coöperation, joint and united effort will be the systematised normal practice, and when a patient needing advice from a medical man will have brought to bear on his case all the resources for diagnosis and treatment which are at the disposal of a great hospital.

Training of the Medical Student of the Future.

I do not anticipate that this will be substantially longer in *duration* than it is at present. I certainly do not think it should be, for the sooner the energy and optimism of youth are given their outlet in the world the better for their possessor and better, I think, for the world. But while the length of the course at a medical school will be substantially the same as at present, its *character* will differ in some important respects. In the first place, with the raising of the standard of science teaching in our public and secondary schools I should expect that the medical student of the future will enter upon his course with a grounding in physics, chemistry, and biology which is at least up to the standard now exacted for the First M.B. Examination. He will thus gain additional time to devote to the fundamental sciences and the methods of their application in the investigation of disease prior to his admission to the wards. I have already given some indications of the lines which I think that teaching will follow. The physiology will be more comprehensive than is now possible, and it will include a good amount of biochemistry and biophysics. Physics will be carried a good deal higher than the present elementary standard and will be so shaped as to have a very definite bearing on the subsequent clinical work. I should expect, too, more emphasis to be laid on pathology. On the other hand, I venture to think that the study of materia medica is far too detailed and extensive, and I would hazard the opinion that at least two-thirds or three-fourths of the British Pharmacopœia could with advantage be discarded. When the student had entered the wards he would get what he gets now—a sound general grounding in medicine and surgery, but after this stage he would be required to make a choice, and his subsequent course would vary according to the career which he ultimately had in view. By this time it would be realised that it was not humanly possible to cover everything, and that instead of having a nodding acquaintance with several specialties the more excellent way would be to give the student the best possible training in general medicine and surgery, allowing specialisation only in those subjects to which the student intends to devote himself in his practice. Thus the man proposing to take up public health work would take up a course comprising subjects like bacteriology, epidemiology, statistics, hygiene, &c. The surgeon would naturally take more anatomy, &c. The specialists would likewise take such subjects in which they intended to specialise. Each student would thus have at his medical school courses for a thorough training in the sciences on which the art and practice of medicine are based, a comprehensive training in general medicine and surgery, and a good acquaintance with a certain number of the specialties.

ORGANISATION OF MEDICAL PRACTICE.

What of the organisation of medical practice? That I have, perhaps, foreshadowed to some extent in the training. I think that in the big cities and in fact in most urban areas the medical man practising alone will gradually make way for the group, a partnership or association. It will no doubt vary in size—it might in some cases contain as many as six or more individuals, in others, in the smaller towns, it would be less. The group would be organised on the basis of the division of labour working on the lines of specialisation. The specialisation, however, would not be so intense as to divide the group into water-tight compartments; the training each man would have received in fundamentals and in general medicine and surgery would render him competent to deal with ordinary cases and to recognise anything which necessitated further and detailed investigation and the services of a specialist. These cases would then be handed over to the appropriate specialist of the group, one of whom would certainly be a pathologist, while part or the whole of the group could, when necessary, meet in consultation in cases of any great complexity. In this connexion I foresee an important development. Our so-called "pharmaceutical chemists," who at the present time are simply dispensers and compounders of medicines and vendors of innumerable "patent" nostrums, will be available for the carrying out of many of the chemical investigations necessary in the elucidation of disease. This will be made possible by the education courses and curriculum of the pharmaceutical chemist being improved, modified, and extended. The establishment of the new degree in pharmacy at the University of London will, I trust, help much in this direction.

Associated with each group would be an institution for the reception of patients, which I may call the "health institute" or hospital. It would not be the analogue of the present nursing home, but would approximate more to a hospital in respect of its organisation and its resources, and would be run in association with a group of nurses organised on lines somewhat similar to those of the doctors. The fees would be graduated according to the financial position of the patients, and I do not think that there would be any risk whatever of its financial soundness. It would be linked up with other institutions of a similar nature and with sanatoria up and down the country allowing of the treatment of patients in different climates, and also of a wider choice of specialists.

This coöperative plan is, you will recognise, directly along the lines of development which has in fact already been followed. That is, indeed, one of its merits in my judgment. But it is, of course, much more than a mere partnership based on personal or similar considerations: it is a deliberate association of men trained for the express aim of acting together and of pooling their various attainments, and the "health institute" is a recognition of the fact that modern medicine requires, even demands, coöperative and institutional investigation and treatment. With this it is fairly obvious that a pretty radical alteration in the National Insurance Acts must follow, and I for my own part would not be sorry. I am convinced that under group arrangements such as this it would be easily possible to hand over to the profession the responsibility for the health of the people, and I am sure that the profession would rise to that responsibility.

PUBLIC HEALTH.

I have not time, I am afraid, to deal at any length with the organisation of public health in the future. The present arrangements, in spite of improvements of recent years, are far from satisfactory. There is really no justification for responsibility being divided among three or four different departments of State, and it is difficult to see why the various public services, such as tuberculosis, venereal diseases, vaccination, medical research, &c., are not centralised at any rate in the larger towns, and brought under one roof. Here is a subject in which the medical man of the present can, I think, bestir himself with advantage.

I do not think, if I may say so, that the medical man of the present plays the part which he should do in public affairs, Imperial and local. I know, of course, that the demands on his time and energies are considerable and his leisure scanty, but democratic government will never reach its fullest development unless it can command the services of educated, trained men who are in a position not only to give expert advice on those questions affecting the health of the community which are continually coming up for discussion before Parliament and local authorities, but who are also willing to bear their part as good citizens in all that touches the public weal.

The Medical Man of the Future and the Naval, Military, and Air Medical Services.

I feel a little diffident in forecasting what will be the position of the medical man in the future as regards the Navy, Army, and Air Force. In former times it used to be said that the three fundamentals essential and important in a fighting force were courage, genius, health. First courage, next genius, and lastly, health. Certainly in the wars of former days courage and genius were looked upon as being much more important than health, but commencing with the South African War in 1900 and afterwards in the Great War, health has been looked upon as being quite as essential as the other two. Two primary difficulties have always been met with in the past in connexion with the professional or medical efficiency of the Navy and Army Medical Services. First, administration or the occupation of administrative posts has always been looked upon as being the sure and easier avenue to promotion, especially to the highest offices in the service, whilst the clinical route of approach to promotion, especially to the highest posts, has occupied a very inferior position; and secondly, the clinical facilities available for the regular instruction and practice of the naval and army medical officer have been very deficient. The medical officer of a public service such as the Navy and Army, who is and has been mainly employed in administration, almost invariably becomes from a practice point of view a mere automaton—quite, unable to grasp the essentials for the successful investigation and treatment of disease. Such was the case during the Great War, according to my somewhat extensive experience. In the future I think arrangements must be made whereby a considerable proportion of the civil medical profession shall always be available for immediate service with the Navy, Army, and Air Force, and shall occupy a proper and not a subordinate and inferior position. In addition, extra provision must be made for the regular training of Naval, Army, and Air Force medical officers in well-equipped schools, provided with a sufficiency of clinical material.

V.

FIFTY YEARS OF MEDICINE.

Introductory Address at the Opening of the Medical Session, King's College Hospital, on Oct. 1st,

By Sir DAVID FERRIER, M.D., F.R.S.,
CONSULTING PHYSICIAN TO THE HOSPITAL; EMERITUS PROFESSOR OF NEUROPATHOLOGY, KING'S COLLEGE.

It is now 50 years this day since I last had the honour of giving the introductory address at the opening of the session of the King's College Medical School. Half a century is a long period in one's professional life to look back upon, yet I often find it difficult to realise that so many years have elapsed. It is one of the proclivities—or perhaps infirmities—of age to like to revert to the past; and if I may indulge in this respect for a few minutes, it is not as a *laudator temporis acti*, but in order to draw some lessons which may have a useful bearing on the present and the future.

At the time of which I am speaking—viz., 1874—Listerism was only in its infancy, and but slowly making way against great inertia, as well as much active opposition. For although in 1867 Lister had been successfully applying to surgery Pasteur's doctrines as to the germ theory of fermentation, his views had not yet been generally accepted, or extensively put in practice. Surgical operations were relatively limited in range, and followed by frightful mortality; surgical wards often reeked of suppuration and sepsis; and many surgeons were still operating with instruments, and in garments, swarming with putrefactive germs. As late as 1880—three years after the advent of Lister to this hospital—when my late colleague, Prof. Gerald Yeo and I, at a meeting of the British Medical Association, showed that with antiseptic precautions the most formidable operations could be made on the brain without risk of the otherwise fatal meningo-encephalitis, there were not wanting eminent surgeons and others who shook their heads incredulously, or expressed their entire disbelief in the germ theory of sepsis. It is difficult for those of you of the present generation to realise the state of affairs not only in surgery, but in other departments of medicine 50 years ago. Our remedies were for the most part purely empirical. The science of pharmacology was only in its infancy, and we could give little or no reason for our prescriptions beyond the fact that they had been found useful by our predecessors. Yet it should never be forgotten that, so far as pure observation could carry them, unaided by other than the most simple instruments of precision, the physicians of old have never been surpassed in their delineation of the symptoms and natural history of disease, and skill in prognosis. The names of Sydenham, Heberden, Bright, Matthew Baillie, and many others among our countrymen, will compare favourably with any of those of the present day. If their theories as to ætiology and pathology were often founded on what we can now smile at as crude assumptions, we need not pride ourselves unduly on our superior knowledge. Considering the transformation or revolution that is taking place at the present day in our conceptions of life, matter, and energy, it is not unlikely that some one of my audience, reviewing the progress of medicine 50 years hence, may have to comment in a similar manner on the primitive character of our present-day notions on many problems of health and disease. Still, when all is said, I think, as regards scientific medicine, we may, like the son of Tydeus, reasonably "boast that we are much superior to our fathers."

The Value of Experiment.

Now what has been the principal cause of this superiority? Unquestionably, in my opinion, it has been obedience to the illustrious Harvey's injunction to the College of Physicians to "search out the secrets of Nature by way of experiment." It is by the application of the experimental method to the elucidation of vital problems that within the last half century medicine has been so transformed that its progress has with truth been characterised as a veritable romance. As the late Lord Fletcher Moulton in his evidence before the Royal Commission on Vivisection has said: "No man who knows anything of science has any doubt whatever that the right way to advance knowledge is by experiment. When we are reduced to observation, science crawls. When, and in proportion as, you can use experiment, the science advances rapidly. The more complex the subject is, the more factors there are at work, the more essential the experimental method is, and the most complex of all phenomena are those that relate to human beings."

What can be considered more marvellous than the powers recently conferred on medicine by physiological experiment on the ductless glands and their secretions? As the late Sir William Osler has picturesquely expressed it: "No such miracles have ever been wrought by physicians as those which we see in connexion with the internal secretion of the thyroid gland. The myth of bringing the dead to life has been associated with the names of many great healers since the incident of Empedocles and Pantheia; but nowadays the dead in mind, and deformed in body, may be restored by the magic wand of science. The study of the interaction of the internal secretions, their influence on development, upon mental powers, and upon disorders of metabolism, is likely to prove in the future of a benefit not less remarkable than that which we have traced in the infectious diseases" ("The Evolution of Modern Medicine"). Osler's prediction has been amply verified within the few short years since his lamented death by that most recent triumph of experimental vaccine, the discovery of insulin, the "elixir vitæ" to thousands of sufferers, living precarious lives, with fatal coma, like the sword of Damocles, threatening to descend on them at any moment. How this appears to unprofessional eyes may thus be described in the words of Lord Knutsford in the recent debate in the House of Lords on the Dogs' Protection Bill: "You see a patient come in to hospital with large eyes, sunken face, and stooping figure. He is given insulin. It is not a conjuring trick. It is a miracle. In quite a short time the man is bright and happy and smiling again, and his disease is forgotten."

The Work Ahead.

But while we can boast of triumphs such as these, we cannot afford to rest and be thankful. The problems that demand solution are many and urgent. Though we know a good deal as to the characters, mode of growth, and dissemination of many of the infective germs, we as yet know little or nothing of others—the so-called filter-passing germs—and still less any satisfactory method of combating their ravages. Our knowledge of cause unfortunately outruns our ability to prevent or cure. The tubercle bacillus was discovered over 40 years ago; and yet, in spite of all our efforts, it slays its thousands every year; and the same has to be said of other diseases of men and animals, which cause incalculable loss of health, wealth, and life. The state of affairs is still worse in regard to diseases of which we know neither the cause nor the cure, such as disseminated sclerosis, progressive muscular atrophy, paralysis agitans, and the like. Most prominent of all in the eyes of the world at the present moment is the problem of cancer, which unhappily seems to increase as civilisation advances. Our hopes were recently raised high that here again Toronto had achieved another magnificent triumph, only to be shattered by further examination. We need not, however, despair, only we must guard against being over-sanguine as to the results of investigations of a purely ad hoc character. These will no doubt narrow the approach and pave the way to the ultimate solution; but it is quite possible that the key to the mystery will, after all, be given by some research undertaken for its own sake, or without any obvious bearing on the problem in hand. Many such instances might be quoted. It would, for example, seem a far cry from a jelly-fish to a human being, yet, as Lewis has recently shown, Romanes's experiments on the bell of the Medusa have furnished the explanation of that most dangerous state of the human heart, auricular fibrillation, and the rationale of its treatment.

Straw for the Bricks.

The history of science affords abundant illustrations of the fact that the most important and far-reaching consequences may flow from apparently insignificant beginnings. There is not a single addition to natural knowledge, physical, chemical, or biological, which does not find its appropriate place in the grand edifice of science and the powers it confers on mankind. The conquest of ignorance is our only sure defence against the diseases and other evils with which we are constantly threatened and assailed. Yet, though pure science receives much lip-homage, it receives but little general support, and medico-biological research in particular not only little support, but much ignorant opposition unless it gives immediate protection against disease, or promises absolution from the consequences of sins against the laws of health and indulgence for future transgressions. One is constantly met with the question, "What is the *practical* object of your proposed research?" If you cannot make this sufficiently plain to the unenlightened, you are apt to be regarded as a visionary, out of touch with the realities and needs of the world. This attitude is unfortunately not confined to the laity, but is all too frequently found even in our own profession.

While there is no branch of science which does not bear directly or indirectly on practical medicine, that which, above all others, most intimately concerns you in your study of disease is physiology—appropriately termed the Institutes of Medicine. It is only by an intimate knowledge of the functions of the various tissues and organs of the body and their inter-relations, practically applied in the clinical wards and pathological theatre, that you can appreciate the true nature of disease and the meaning of its symptoms. And it is this alone that can furnish a sound basis of independent judgment, and secure freedom from slavish adhesion to any system, or blind obedience to the words of any master.

Unchanging Essentials in the Art of Medicine.

It would, I think, be a great misfortune if the increased facilities which scientific methods have provided us with for the diagnosis of disease, such as the X rays, electrocardiograph, biochemical and other tests, should lead to atrophy of the *tactus eruditus* and other trained faculties of the skilled practitioners of old, or to neglect of the simple or unaided methods of diagnosis, such as percussion, auscultation, and the like. It would not be well if a surgeon were unable to diagnose the existence of a fracture or dislocation without the aid of a radiogram; or for a physician to be dependent on similar aid for the recognition of a consolidation of the lung, or the existence of a tumour in the brain. Some indications, however, have been noted by our examiners of a tendency on the part of the younger generation to neglect the simpler methods and to rely too exclusively on aids which may not be available at the critical moment. Delicate physical and chemical apparatus are necessary in the clinical laboratory, but the results must be incorporated with those of other methods, and capable of application by the practitioner in the ordinary course of his work. The various methods should supplement but not supplant each other, and as we see clearly only what we are prepared to see, clinical vision should be sharpened rather than dulled by the light of science.

Nor does scientific pharmacology necessitate the abandonment of purely empirical methods which long experience has proved to be of value in the relief of suffering. The theories on which they have been based may appear to us fanciful, and we may not be able to give a rational explanation of their *modus operandi*, but it would be foolish to discard them. There are many remedies, now out of fashion, which are still relied on, and apparently on good grounds, by physicians of ripe experience and sound judgment. Nor should the study of the scientific bases of medicine ever be divorced from the most thoroughgoing study at the bedside. The human body is a much more complex organism than that of the lower animals, and infinitely more so than any mere physical or chemical compound. The agents employed in the treatment of disease do not necessarily act in vivo only as they do in the test-tube. The living body is, as Prof. H. H. Dale has said, in many ways an essential partner in its own cure. And, more particularly, the psychical side of man—the impulses and emotions by which he is swayed—constitutes a factor which highly complicates the action of all the remedies of the Pharmacopœia. Though much valuable work has been and is being done in this direction (Lange, Pavlov, Cannon, and others), we as yet know comparatively little as to the mode of origin and channels of transmission of those corporeal influences; but it is certain that the pleasurable emotions such as faith and hope *exalt*, while the depressing emotions, such as fear, doubt, and anxiety, *depress* all the vital functions. How to promote the one and combat the other is often more a mark of therapeutic skill than a judicious selection from the Pharmacopœia.

SUGGESTION IN HEALING.

This has long been implicitly recognised and acted on in daily life. Prescriptions, apart from any intrinsic value they may possess, are also largely vehicles of suggestion. Everyone knows that a prescription by the eminent physician, Sir A. B., of Harley-street, may have a very different therapeutic value from exactly the same prescription given by Mr. C. D., of Little Pedlington. And there is a grain of truth in the remark by Petronius Arbiter, the cynical courtier to the Emperor Nero, that a physician is "only a satisfaction to the mind." I have no intention of critically examining the respective merits or demerits of the various methods of suggestion, but would merely remark that suggestion, however induced, should be kept in its proper place. No amount or kind of suggestion will, for instance, reduce a dislocation or remove a tumour from the brain. Apart, however, from special methods of suggestion, however commendable some may be in certain circumstances, it must ever be the endeavour of the physician to mobilise all the defences of the organism, psychical as well as physical, against the attacks of disease and for the restoration of health. There is one factor within reach of you all—surpassing all others in importance—and that is *a thorough knowledge of your work*. This by itself can outweigh a multitude of defects, and will constitute the best and most solid basis of that self-confidence and decision which are so necessary to inspire faith and trust on the part of those with whom you have to deal.

A CRITIQUE OF THE SURGICAL TREATMENT OF ANGINA PECTORIS.

BY SIR JAMES MACKENZIE, M.D. EDIN., F.R.C.P. LOND., F.R.S.

THERE has, in recent years, been an endeavour on the part of surgeons to seek for new fields, and there seems no region of the body which the surgeon is not prepared to invade. The impression has got abroad that the feats of the surgeon are indications of the progress of medicine. When operations are carried out with a full knowledge of the morbid conditions which it is intended to relieve, and with a knowledge of the functions of the structures which the surgeon cuts in his operation, there might be some reason for regarding such surgery as an example of the progress of medicine, but when the surgeon is profoundly ignorant of the morbid condition for which he operates, and of the functions of the structures which he mutilates, it is impossible to conceive anything more detrimental to progress. At one time the surgeon was supposed to have a knowledge which would enable him to make not only a diagnosis but a prognosis, so that he could tell whether his interference would be to the patient's benefit. But the trend of modern medicine with its specialism is, that the surgeon dispenses with this kind of knowledge and relies upon others for instructions when to operate.

This tendency is well illustrated in the surgeon's excursions into the treatment of angina pectoris. I do not suppose there is a surgeon who would even pretend to understand the morbid condition which gives rise to the symptom-complex called angina pectoris. The knowledge of the functions of the vagus and the sympathetic which the surgeon cuts is so imperfect that neither he nor the physician who advises him understands but a fraction of the functions of these nerves.

Present Knowledge of Causes of Heart-Pain.

Before such a formidable and dangerous operation is undertaken it is advisable that the state of knowledge of the diseasesd conditions which are associated with, or give rise, to angina pectoris should be recognised.

It is a reflection on the state of medicine that such a clamant, distressful, and universal symptom as pain should be so little understood, that it is impossible to tell what the agents are which are concerned in its production, and it is not even known how to proceed to find them out. It is recognised that there are structures which, when mechanically stimulated, produce pain, and other structures which when so stimulated do not produce pain, but which by other forms of stimulation do give rise to pain. Anatomy cannot tell us the difference in the nerve-supply which this observation indicates, nor can physiology tell us the vital processes concerned in the production of pain in organs that cannot be mechanically stimulated to produce pain. The consequence of this state of affairs is that a subject like angina pectoris is still a matter for vague speculation, and the employment of such drastic treatment as a surgical operation for a condition so little known does not redound to the credit of medicine.

The aim of surgical treatment is not to "cure" the disease but, by cutting the nerves which convey impulses from the heart to the central nervous system, to prevent the patient feeling pain. These nerves are the sympathetic and vagus—two nerves whose functions are as imperfectly understood as the nature of angina pectoris. It must be remembered what little is known of these nerves from experiment is limited practically to the *efferent* part of the nerve. The part played in the economy by the *afferent* part is unknown save for some crude experimental results—and these are imperfectly interpreted. It is the *afferent* nerve which the surgeon seeks to cut, and so this operation is one where structures are cut whose function is unknown, beyond the fact that they convey impulses from the heart to the central nervous system for a condition that is still the subject of speculation.

After-History of 1000 Patients.

In an analysis of over 2000 patients who suffered from heart pain lately undertaken by me, the notes of 1000 were discarded as the histories of the patients after the notes were taken were not satisfactorily recorded. In the remaining 1000, the future course of the health of the patients was recorded with sufficient precision to enable certain conclusions of value to be drawn.

The patients could be divided into two groups. One, the smaller, in which the pains were not associated with any disease of the heart, and another group where such disease was present. The pain, its situation and onset, and the other symptoms associated with it, were the same in both groups.

In angina pectoris the chief structures concerned are the nervous system and the tissues of the heart, and disturbance of either may result in pain. In the former group the pain is due to disturbance of the nervous system. It has long been recognised that in certain forms of ill-health, symptoms due to disturbance of organs which are themselves perfectly healthy may result from disturbances of the nervous system. The most striking of these is vomiting. Pain also is a frequent expression of a similar form of disturbance, so that the pain and other symptoms associated with angina pectoris are not infrequent in people whose hearts are healthy, but who suffer from ill-health which disturbs the nervous system. The vast majority of these patients are women under 50 years of age. During the war numbers of young soldiers showed all the signs of angina pectoris, but they all suffered from some infection, often too obscure for identification, but which in some instances was ultimately found to be "trench fever."

I have followed some hundreds of these cases of "secondary angina" for many years, and not one has died from an affection of the heart—the heart symptoms in every case disappeared, many were restored to health, others were crippled from the persistence of the original complaint or from some of its effects.

In the larger group, "Primary Angina Pectoris," there are morbid changes in the structures of the heart which are progressive. The first appearance of the signs of angina is, as a rule, insidious, being usually a slight sense of discomfort, felt across the chest generally on making some form of effort which had hitherto been performed with perfect ease. At first the discomfort may appear at rare intervals, and is brushed aside as indigestion or ignored. In course of time it becomes more frequent, more easily provoked, and may culminate in violent pain, occurring in "attacks." There may only be one severe attack, or there may be a series coming on at intervals for days, weeks, or months. Complete rest being enforced for a period the attacks subside and the individual may be free from attacks for many years, or there may be a recurrence in a few months, but the tendency never disappears—the attacks being apt to come on under particular circumstances, as on walking after a meal, or against a cold wind, or on first starting after a rest—the patient nevertheless being able to lead a useful life.

Morbid Changes Found.

In nearly every instance slowly but surely the response to effort becomes restricted and the pain tends to appear with ever-increasing facility. When death arrives, it may be many years after the onset, morbid changes are invariably found at the post-mortem examination, although the physical examination during life may have given no signs of anything amiss.

The morbid changes in the vast majority of cases are found mainly in the coronary arteries and in the muscle of the left ventricle. If these changes and the effects they produced during life be studied, some idea can be formed of what "angina pectoris" signifies. Although no two cases are identical, in regard to the part affected, yet the nature of the morbid process and its resultant effects are remarkably alike in the majority. These consist of such narrowing of the lumen of some part of the coronary artery, that the supply of blood to the muscle is so diminished as to impair not only the functional efficiency of the muscle, but to lead to degeneration and destructive changes in the heart muscle.

If it be borne in mind that the healthy coronary artery is very distensile, and that when the heart is called upon to increase its work in response to effort, there is required a greatly increased supply of blood, not only is the reason for the distensile artery apparent, but also the effect which is bound to follow when the lumen of the artery is narrowed and its walls become rigid.

Angina pectoris is the subject of investigation at the St. Andrews Institute, and so far, post-mortem examinations have been made on seven patients, of which the three figures are typical. The results of these examinations are like the 50 odd post-mortem examinations I had made on my own patients, and correspond with numerous published records since Heberden and Jenner's day, so that they may be taken as typical of the more common forms of angina pectoris.

If one inquires what were the evidences shown by such damaged hearts during life, pain, especially in response to effort, was common to all. The processes which led to these morbid changes must have taken many years. Indeed, one can reasonably infer that they must have been going on for many years before the response to effort was so diminished as to produce the early signs of distress. It is therefore impossible to tell the duration of the morbid processes that lead to angina. The duration of the symptom of "angina pectoris" can only be estimated from the time that pain appeared, and therefore its onset has no relation to the onset of the morbid process which induces the pain. As this symptom depends not only on the morbid condition, but also on the exposure of the individual to conditions that favour the production of pain, the history of the onset is of doubtful value for any purpose. One of my patients reached the age of 80 before he had any pain, and it came on because he was forced to run 100 yards at the top of his speed—an amount of effort he had not undertaken for 20 years.

The Removal of a Danger-Signal.

Study of the morbid changes in the hearts of patients who have suffered from angina pectoris brings clearly before the mind what the condition is that the surgeon is to treat when he proposes to operate. No one would claim that he can "cure" angina pectoris by operation or any other procedure. All the surgeon could hope to do would be to cut the nerves that convey the impulses which give rise to pain, from the damaged heart to the centre of consciousness.

Is such a procedure wise and for the best interest of the patient? Putting aside the question of what damage may be done by the cutting of such important structures as the sympathetic and vagus nerves—nerves whose functions, be it noted, are, even yet, scarcely understood—and apart from the danger of the operation and the possible damage which may result from the mutilation that accompanies such an operation, the question arises. Is it to the best interest of the patient that he should be deprived of a signal, it may be, of great value?

If we look at these hearts it is manifest that they could only accomplish a small part of the work which a heart should perform. Muscles like the heart can be forced to work till a stage is reached when they can do no more work. When this stage is reached, no blood can be thrown out and the consequences of a failure of output are unconsciousness and death. Moreover, one of the provoking causes of ventricular fibrillation is a defective blood-supply and this is a common cause of death in angina pectoris.

On the other hand, a sign given out by muscle when exhausted, and particularly when forced to work when the blood-supply is defective, is pain. In the early stages of the suffering, the failure to recognise the significance of pain often leads the individual to persist in efforts beyond the heart's capacity, with the result that the exhaustion of the heart muscle reaches a stage that pain of a great severity is induced which, as already said, may last for a considerable time—until, indeed, a measure of strength is restored to the heart muscle. Great numbers of patients get to recognise the significance of pain and by taking thought of the circumstances that provoke it, can lead useful lives free from distress for many years.

One could cite many instances which throw light upon this matter, but one may suffice as it illustrates several very important features which have not received that consideration which is their due. A man began to suffer from angina pectoris, the pain coming on only in response to effort. An examination revealed nothing but a systolic aortic murmur. A year later he began to have attacks of loss of consciousness, which were found to be due to partial heart-block. After some months the block became complete, the pulse being constant at the rate of 30 per minute. The attacks of loss of consciousness ceased and he suffered no more from pain. On effort he could do less, and was stopped on account of a sensation of weakness and breathlessness. He dropped down dead three years after the first appearance of pain. At the post-mortem examination the aortic valves were sclerosed, and the sclerosis extended up the aorta and embraced the mouths of the coronary artery, which was rigid and narrowed, it extended down into the heart muscle and had destroyed the auriculo-ventricular bundle.

It is thus seen that these diverse phenomena, the aortic systolic murmur, angina pectoris, and heart-block, were all produced by the same morbid process. But the point of interest here is the pain and its cessation. The narrow, rigid orifice of the coronary artery manifestly would not dilate to permit an increase of blood to meet the requirements of the muscle, and in consequence the muscle, like all muscles forced to work with deficient blood, gives rise to pain.

When complete heart-block set in, it was impossible for the ventricle to be stimulated to increased effort, for the rate of the ventricle never varied from 30 per minute at rest or on violent effort. Consequently there was no demand for an increased blood-supply, and effort was limited, not by pain, but by sensations provoked by a diminished output of blood from the heart.

Pain not in Itself Dangerous.

Great as the distress is which pain produces, pain itself is in no sense a dangerous symptom. It may be associated with conditions which are dangerous, but such dangers are not rendered less dangerous by easing the pain. Indeed, it often is a beneficent agent, in directing attention to the presence of a morbid condition, and more especially in warning that the persistence of a particular condition is harmful. It is in this latter sense that pain is beneficent, and used in conditions like angina pectoris it forms one of the most helpful indications for preserving the efficiency of the heart. It is manifest that the amount of work the damaged heart can perform is limited, and the indications for treatment are to save the heart muscle from over-exertion. The measure of the amount of work is found in what can be done without distress. It is well recognised that, before pain arises, there are faint signs experienced which indicate that with persistence pain will be induced, so that taken as a signal to desist, the individual then knows what amount of effort it is safe for him to undertake. In this way many people are able to pursue even laborious occupations with no discomfort and no danger.

To remove this valuable indicator in the present state of our knowledge is, to my mind, extremely hazardous and bad practice. When a better knowledge is acquired it may be found of value in some instances, but so far as I can see there are no indications which would enable suitable cases to be recognised. I have carefully studied the published records of cases operated upon, and these records show no consciousness of that division of angina into primary, with varying degrees of morbid changes, and secondary, with no affection of the heart. Moreover, the records both before and after operation are given so imperfectly that no clear conception of the nature of the condition can be ascertained, except those who died in consequence of the operation.

It must be remembered that, though pain may be relieved, the patient is not "cured," nor is the progress of the disease stayed. As the vast majority of patients live for many years after the first appearance of angina pectoris, the fact that a patient is free from pain for months or years is not evidence that his condition is improved. Such patients as have been operated upon and have recovered from the operation would afford the opportunity for investigation, not only of the results of the section of nerves, but of the response of the heart to effort, to find out, not only how the heart's movements are affected, but what are the sensations which warn the patient of the heart's exhaustion. So far the published reports fail to afford this information.

Need for Re-Investigation of Cardiac Nerves.

The attempt to find a reason for employing surgery in the treatment of angina pectoris has revealed that very little of practical value is known about the functions of the vagus and sympathetic nerves, and in consequence plans are being formed for the reinvestigation of these nerves. Before such a laudable enterprise be entered upon it would be well for the investigators to review all the work that has been done on this subject and to study the reasons why so little is still known. It will be found that a great number of experimental observations have been made and certain reactions have been detected, but the interpretations of these reactions are imperfect and unreliable. Thus, an increase or a decrease in the rate of the heart may have been recorded, but it is not known what structures were involved in bringing about these changes in rate. The interpretation which holds the field to-day was made at a time when the presence of the conducting system was not even suspected. No movement of the heart can take place without the participation of this system, and so little is known of this system that its study can scarcely be considered to be begun.

Such observations that have been made on these nerves have been almost entirely limited to the *efferent* nerves. In clinical medicine, and especially in dealing with angina pectoris, it is the part played by the *afferent* nerves that has to be known, and except the results of some crude badly interpreted experiments, nothing is known of the afferent system of nerves. The reason for this is that the afferent system of nerves of the whole body are beyond the range of experimental observation. The most important functional part of the afferent nerve is situated in the fibrils at its peripheral distribution—in the skin, and in the substance of the organs—and it is the manner in which these peripheral fibrils are stimulated which requires to be found out. In experiment when the nerve is cut, this essential part is cut off and cannot be replaced by electrical stimulation of either cut end. It would be as reasonable to investigate sight by cutting off the eyeball and stimulating the stump of the optic nerve as to investigate the function of an afferent nerve by cutting it and stimulating its stump.

The clinical evidence of the part played by the afferent nerves is abundant. The whole series of phenomena in angina pectoris are but evidences of their activity—the pain, the constriction of the chest, the flow of saliva, and other signs are all evidences that impulses have arisen in the heart and have been transmitted to the central nervous system. So little, indeed, is known that the source and nature of these impulses is still a matter of controversy.

Such matters as these must be considered by would-be investigators, as well as the reason for the defective knowledge which continues in spite of all attempts to find out the function of these nerves. It is likely that it will be found that some concept other than those which have guided research in the past must be employed, and it may come to pass that such an investigation can only be carried out by using the opportunities of the clinical observer.

THE DANGERS OF UNABSORBABLE SUTURES IN GASTRO-ENTEROSTOMY.

WITH REPORT OF A CASE.

BY G. A. UPCOTT-GILL, F.R.C.S. EDIN.,
MEDICAL SUPERINTENDENT, QUEEN'S HOSPITAL, SIDCUP;
AND
H. B. JONES, M.R.C.S. ENG.,
RESIDENT SURGICAL OFFICER TO THE HOSPITAL.

THE following case illustrates the unfortunate results of the usage of thread or silk as a suture in entero-anastomosis.

The patient, a soldier, aged 37, was admitted to Queen's Hospital, Sidcup, Kent, on Sept. 3rd, 1923, with a history of abdominal pain and vomiting for six years, and of a perforated duodenal ulcer and laparotomy on March 29th, 1922, and a subsequent laparotomy with posterior gastro-enterostomy on Oct. 10th, 1922. He stated that since the last operation he had had constant recurrence of pain and vomiting, the attacks lasting three days to two weeks, with periodical intermission.

Symptoms.—(1) Pain, gnawing in nature, in the left half of the epigastrium, lasting two to three hours, but eased by taking food or by lying down. Patient woke about 10 P.M. to 3 A.M. every night through discomfort. He was relieved by hot fluids, bismuth, or hot flannels. (2) Vomiting was rapidly induced by the pain, which it relieved; dark in colour, bitter, slimy in nature. Heavy foods—e.g., meat, potatoes, &c.—accentuated the pain and vomiting. (3) Hæmatemesis. There had been three attacks of hæmatemesis since the last operation. Bowels not constipated; appetite very good; had lost weight.

Abdominal Examination.—Two well-healed laparotomy scars; no hernia. Splashing and gurgling over a much dilated stomach; tenderness in the left half of the epigastric region with slight general abdominal rigidity. Nothing else abnormal detected.

X Ray and Bismuth Meal (screen and film).—Duodenal cap normal and no tenderness in this region. Large intestine slightly ptosed. First fractional test-meal (Oct. 15th, 1923): Increased total acidity and free HCl—viz., 60 to 146 per cent. From Oct. 16th to Dec. 15th, 1923, patient was kept under observation with light fish diet, large doses of alkalis and belladonna, but showed no improvement in his symptoms or general condition. Second fractional test-meal: Showed marked hyperacidity in excess of Oct. 15th. Thus the total acidity varied from 55 to 80 per cent.; in two and a quarter hours it reached 100 per cent. Free HCl 55 per cent. (0·205 to 0·235).

General Health.—The man looked ill and wearied; muddy complexion. Tongue furred, teeth fair, pharynx congested. Is of alcoholic habit. Nothing abnormal in chest, renal, or nervous systems.

Diagnosis.—The recent history of characteristic pain and vomiting, the hæmatemesis, the marked hyperacidity despite a previous gastro-enterostomy, pointed to fresh ulceration, probably gastro-jejunal.

Operation (Jan. 4th, 1924).—Anæsthesia, gas and oxygen induction followed by spinal anæsthesia (stovaine). Supra-umbilical incision. On opening the peritoneal cavity many adhesions were found. All of these were separated and ligatured or transfixed. The stoma of the old posterior gastro-enterostomy was examined and found barely to admit two fingers, and to have a hard, unyielding edge. Palpation of the stomach did not disclose any other abnormality. The stomach was then opened above the cardiac side of the anastomotic opening. There immediately presented a dark, hard mass the size of a cherry (afterwards found to be blood-clot), connected to the stoma by a long, loose pedicle. This was recognised as an old thread suture. The gastric opening was then closed and another opening made which gave better access to the anastomosis. It was now obvious that the thread suture had been used for the previous gastro-enterostomy, and had partially ulcerated out, so that the two strands were still connected to the anterior and posterior lips of the stoma, while the unattached ends, matted up with old blood-clot, moved freely in the gastric cavity. There was a large crater-like ulcer involving the anterior and posterior walls of the stoma for about two-thirds of the circumference. This extended upwards and downwards into the stomach and jejunum respectively. The whole anastomosis, with an inch of stomach and jejunum, excised. New posterior anastomosis made, using 30-day catgut and Souttar's needles. Scar of old duodenal ulcer almost healed, but slight pyloric stenosis persisted. Nothing else found. Abdomen closed in the usual manner.

Progress after Operation.—The patient made an uninterrupted recovery, and was allowed to get up in 28 days time. He was given large doses of alkalis and paraffin with an occasional aperient, and kept strictly on fish diet. He occasionally had a sharp pain in the upper right abdominal quadrant on turning over, but this has gradually decreased and should disappear.

Conclusions.

This case very aptly illustrates two important points (to which Woosley [1] drew attention in a similar case). (1) That the use of unabsorbable suture is a mistake in gastro-intestinal surgery; the suture of choice is chromic or tanned catgut. (2) If a gastro-jejunal ulcer develops it should be treated surgically and not medically—i.e., by excision of the original anastomosis and the ulcer, and a reconstruction nearer the lesser curvature. Both Walton [2] and Gronnerud [3] have given up silk or thread suture, and lay stress on their experience that since abandonment in favour of catgut they have had no incidence of peptic ulcer. Wright [4] describes a case where silk was used for an anterior gastro-enterostomy which was followed in the same year by a gastro-jejunal ulcer. This was infolded, but eventually perforated. Complete excision and a posterior gastro-enterostomy had then to be carried out, with no recurrence of any trouble two years later. He makes the striking statement that his records show 13 cases of gastro-jejunal ulceration due to silk suture. Adams [5] records the occurrence of a gastro-jejunal ulcer three years after anastomosis; a silk knot was found in the centre of the ulcer.

With such striking evidence before him of the disasters liable to follow the use of unabsorbable suture the surgeon should surely turn to other material. Thirty-day catgut, preferably on a Souttar's needle, supplies the want.

LESIONS OF THE TRACHEA IN PULMONARY TUBERCULOSIS.

BY FREDERICK R. G. HEAF, M.D. CAMB.,
MEDICAL SUPERINTENDENT, WARWICKSHIRE KING EDWARD VII. MEMORIAL SANATORIUM.

THE anatomical situation and inaccessibility of the trachea may account for the small amount of consideration which it has received in cases of pulmonary tuberculosis. Yet by virtue of its position it certainly deserves attention, as it is a channel of considerable length through which many virulent organisms pass on their way to or from the lungs.

My interest in the trachea was first aroused by noticing its condition in a series of 133 autopsies on cases of pulmonary tuberculosis at Colindale Hospital, Hendon. In this series I found the trachea showed abnormal features in 44 per cent. of the cases. A small amount of congestion of the mucous membrane was not taken into account in arriving at this figure, as it was present in almost all the cases.

The lesion varied from a slight œdema of the mucous membrane to a general ulceration of the whole surface, and it was therefore possible to form a good idea of the sequence of events. The mucous membrane becomes increasingly congested until it is a deep purple in colour and considerably thickened by œdema. The surface then begins to desquamate and small superficial ulcers form. These gradually coalesce so that a large irregular shallow ulcer is formed, having a slightly raised edge but with very little induration. The walls are ragged and soft, and are surrounded by an area of deeply congested tissue. The lesion is generally confined to the area just proximal to the bifurcation of the trachea, but occasionally assumes a diffuse form, the whole surface of the trachea becoming covered with numerous irregular shallow ulcers.

In 68 per cent. of the cases in which ulceration was present the lesion was more pronounced on the right side, but occasionally it becomes localised in the middle line and then the ulceration assumes a more penetrating character, and the lesion is deep with indurated walls. In one of my cases the base of the ulcer exposed the pre-tracheal muscles and fascia over an area half an inch in diameter, almost constituting a spontaneous tracheotomy. The relation of ulceration of the trachea to that of the larynx was worked out in order to determine the relation between them, but it was found that in the 58 cases which showed a pathological condition of the trachea the coexistence of definite ulceration of the trachea with infiltration or ulceration of the larynx occurred in all but two cases, although in the 81 cases of laryngeal tuberculosis (both extensive and slight) the trachea escaped 25 times. This compares fairly favourably with the Brompton Hospital figures, in which series of 214 cases the trachea was affected and the larynx escaped 13 times, but 74 cases showed ulceration of both larynx and trachea.

On reviewing the clinical notes of the cases which exhibited gross tracheal lesions, I found that all the patients had complained of a loud distressing cough of a paroxysmal character and very refractory to treatment. With the cough there was deep-seated retrosternal pain and a raw aching sensation across the chest after a bout of coughing. All the cases suffered from dyspnœa and a feeling of tightness across the chest. None exhibited any superficial tenderness over the sternum. Generally there was little sputum, and the lungs at autopsy displayed extensive fibrosis.

Treatment seems to have been difficult and at most only palliative, but a fair amount of relief from the painful bouts of coughing was obtained by frequent insufflations of pulv. anæsthesin and orthoform in equal parts, administered through a Leduc's tube.

ANTIPNEUMOCOCCAL SERUM IN THE TREATMENT OF LOBAR PNEUMONIA.

AN ANALYSIS OF TWENTY-SEVEN CASES.

BY A. I. G. McLAUGHLIN, M.B., CH.M. SYD.,
LATE RESIDENT MEDICAL OFFICER, CITY OF LONDON
HOSPITAL FOR DISEASES OF THE HEART AND
LUNGS, VICTORIA PARK, E.

THE modern treatment of pneumonia with antipneumococcal serum dates from the discovery of the pneumococcus in 1884 by Fraenkel.[1] Early attempts at serum therapy include those of G. and F. Klemperer[2] (1891), Foa and Scabia [3] (1892), Washbourn [4] (1897), Pane [5] (1897), and Neufeld and Händel [6] (1912). Truche, Cramer, and Cotoni [7] in 1911 demonstrated the virulence of the pneumococcus in the mouse, and thus originated a reliable method of isolating the organism from the sputum. In 1913 Dochez and Gillespie [8] classified pneumococci into four groups by means of immune sera. Avery, Chickering, Cole, and Dochez,[9] of the Rockefeller Institute, in 1917 published a monograph concerning the treatment and prevention of lobar pneumonia by means of antipneumococcal serum. Among later important publications may be mentioned a monograph from the Pasteur Institute by Cotoni, Truche, and Mlle. Raphael [10] (1922), and a report to the Medical Research Council by Prof. E. E. Glynn [11] (1923).

The Clinical Material.

The present series consists of 27 cases of lobar pneumonia (Series A) admitted to the hospital during 1923 and 1924, and treated with antipneumococcal serum. For purposes of comparison, the last 27 cases of lobar pneumonia (Series B) admitted to the hospital before the introduction of the serum have been analysed. While this group of cases is not regarded as a completely satisfactory control, the comparison with the serum-treated cases is interesting.

In both Series A and B 21 were males and 6 females. The average age in Series A was 31·7 and in Series B 37·2 years. The majority of cases in both series occurred in the months of March, April, May, and June. In Series A the right lung was affected in 17, the left in 7, and both lungs in 3 cases; in Series B the right lung in 13, the left lung in 11, and both lungs in 3 cases. Of the serum-treated cases 3 died, and of those not treated with serum 7 died. Of the 3 deaths in Series A, 2 were in females. The first patient, who was 16 years of age, was admitted on the fourth day of the illness. Pneumococcus Type 2 was isolated from the sputum. Signs of consolidation were present in both lobes of the left lung; 50 c.cm. of Type 1 serum had been given. She died on the ninth day of the illness. The second, a female of 65 years of age, admitted on the eleventh day of the illness with signs of consolidation in both lungs, died 48 hours after admission. The third, a male aged 32 years, was admitted on the fifth day of the illness. Signs of pneumonia were present over the whole of the left lung and the lower two lobes of the right lung. Pneumococcus Type 1 was isolated from the sputum; 250 c.cm. of Type 1 serum were given intravenously, but the patient died 48 hours after admission. The extent of the pneumonic process was confirmed by autopsy. Of the 7 deaths in Series B all were in males. Two were due to empyema (one interlobar), one was due to right lobar pneumonia complicated by alcoholism, and the remaining three cases died from uncomplicated pneumonia.

It is noteworthy that in three cases of Series B empyema followed the pneumonia, while in Series A no cases of empyema occurred. In one case of pneumonia with Type 1 pneumococcus horse serum in large quantities was given in order to determine whether the bulk of serum injected was responsible for the fall in temperature. This patient developed a pneumococcal empyema.

The Serum Employed.

The therapeutic antipneumococcal serum Type 1, prepared by Burroughs and Wellcome, is used. It has been found by American observers that the results given by the specific sera for Types 2 and 3 and Group 4 are not satisfactory, and that the use of polyvalent sera has not been followed by definitely striking results. On the other hand, in France polyvalent serum has been successfully employed, for instance, by Cotoni, Truche, and Raphael.[10] These workers prepare the serum by inoculating animals with virulent strains of pneumococci regardless of their agglutinating type, which they hold is not correlated with their pathogenic properties. A series of animals is inoculated, each with a different strain, and the resulting sera are mixed.

Method of Typing Pneumococci.

The sputum of each patient on admission to hospital is examined for pneumococci, and the type is determined in the following way. An emulsion is made of the sputum in sterile broth and 0·5 c.cm. is injected into the peritoneal cavity of a mouse. If a virulent pneumococcus is present, the mouse usually dies within 24 hours. The peritoneal exudate is washed out with 2 c.cm. of sterile normal saline, and a thick suspension of organisms obtained. A film of the suspension is stained by Gram's method, and examined microscopically to demonstrate the presence of a Gram-positive diplococcus. The suspension is centrifuged at low speed for one minute in order to eliminate most of the cells. After the cellular elements have been removed the suspension of diplococci is tested for bile-solubility to establish the identity of the pneumococcus. The suspension of pneumococci is titrated by the microscopic method against agglutinating pneumococcal sera Types 1, 2, and 3 (B. W.). Dilutions of 1 in 5 and 1 in 10 are made and incubated at 37° C. for 15 minutes. Agglutination occurs in the corresponding type. If no agglutination takes place, the pneumococcus is considered to belong to Group 4.

Incidence of Types of Pneumococci.

Virulent pneumococci were isolated from the sputum in 24 instances. In two of the remaining cases the injection of sputum failed to kill the mouse, and in the third the properties of the organism were not investigated. Of the 24 cases in which virulent pneumococci were found, 14 were Type 1, 4 were Type 2, and 6 belonged to Group 4. All the Type 1 pneumococci isolated occurred in males. No Type 3 pneumococci were isolated. The predominance of Type 1 pneumococcus in this series is in accordance with the findings of Dochez and Gillespie,[8] who found 35 Type 1 pneumococci in 74 cases.

Routine Treatment.

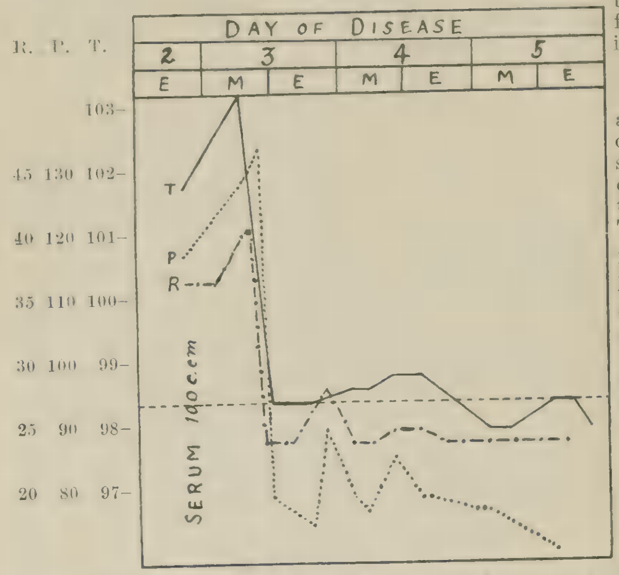
As soon as the patient was admitted to hospital and the diagnosis established, inquiry was made concerning previous injections of serum. When a history of previous injections was obtained, 1 c.cm. of horse serum was injected subcutaneously to determine the presence or absence of protein sensitisation. If no local or general reaction occurred within an hour, 50 to 100 c.cm. of antipneumococcal serum were injected intravenously. This was carried out before the result of the sputum investigation was known. When Type 1 pneumococcus was found in the sputum the injections were repeated every eight hours until the temperature fell to normal and the pulse-rate dropped below 80. If pneumococci belonging to other groups were found, the injections were sometimes continued to observe the effect, but usually they were discontinued. The quantities injected ranged from 50 to 400 c.cm.

The apparatus consisted of two funnels, for serum and normal saline respectively, united by rubber tubing to a Y-shaped glass tube which in turn was attached to the infusion needle by another piece of rubber tubing. The needle was introduced into the vein, and about 5 c.cm. of warm saline allowed to enter the vein, followed by a few drops of serum (warmed to 100° F.) mixed with a further 5 c.cm. of saline. After waiting two or three minutes 5 c.cm. of well-diluted serum were injected, followed by another interval; then 10 c.cm. of diluted serum were run in. If no untoward symptoms occurred after these tentative doses the undiluted serum was then injected slowly. In using this method, recommended by Cruveilhier,[12] no anaphylactic phenomena have been observed. In one case in which the serum had not been diluted symptoms of anaphylaxis occurred during the administration. The symptoms rapidly subsided three minutes after the subcutaneous injection of 1 c.cm. of pituitrin.

Influence on Temperature and Pulse-rate.

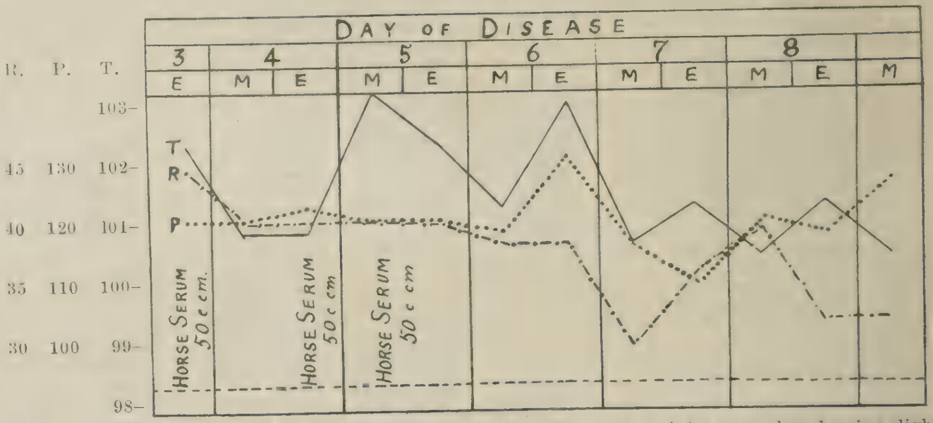
After each injection the temperature fell at least two degrees, and in some cases became normal or subnormal. Concurrently, the pulse-rate and respiration-rate were lowered. As the effect of the previous injection began to wear off the pulse-rate increased, followed by a rise in temperature. Another injection of serum again caused the temperature and pulse-rate to fall. An increasing pulse-rate was taken as an indication that more serum was needed. After the temperature and pulse-rate became normal no more serum was given. In two cases admitted on the second day of the illness an intravenous injection of 100 c.cm. in each case caused an instantaneous drop in the temperature with no secondary rises (see Chart 1). No more serum was required, as the attack appeared to be definitely aborted. Both were definite cases of pneumonia with typical pulse, temperature, respiration ratios, rusty sputum, and the physical signs of commencing consolidation in the lungs. One had well-marked herpes labialis. In these two cases the signs of complete consolidation did not develop. In order to determine whether the fall in temperature was due to the bulk of serum injected one patient was given similar large quantities of horse serum. After each injection the temperature fell about 0·5° but rose again later, and there was no fall in the pulse-rate. As stated above, this patient subsequently developed empyema (see Chart 2).

CHART 1.



L. W., male, aged 24. Acute lobar pneumonia. Intravenous serum, 100 c.cm. on second day of illness.

CHART 2.



W. C., male, aged 18. Acute lobar pneumonia (Type 1). Horse serum intravenously, showing slight fall in temperature after injection, without a corresponding fall in pulse-rate. Developed empyema.

The usual "plateau" type of temperature chart was not seen in the cases of pneumonia treated with serum. An early crisis was usual when large quantities of serum were given at the outset, and with smaller doses a "staircase" descent resulted, each fall corresponding to an injection of serum (see Chart 3). The phenomenon, noted by Lassance,[13] of an "inverse" temperature (the evening reading being lower than the morning temperature) was observed in only one case.

Influence on Physical Signs.

In two cases, as previously stated, where the disease was aborted by large doses of serum on the second day of the illness, the signs of progressive consolidation did not develop. In the cases where the serum treatment was commenced on or after the fourth day of the illness, however, the signs developed in the usual way.

Serum Reactions.

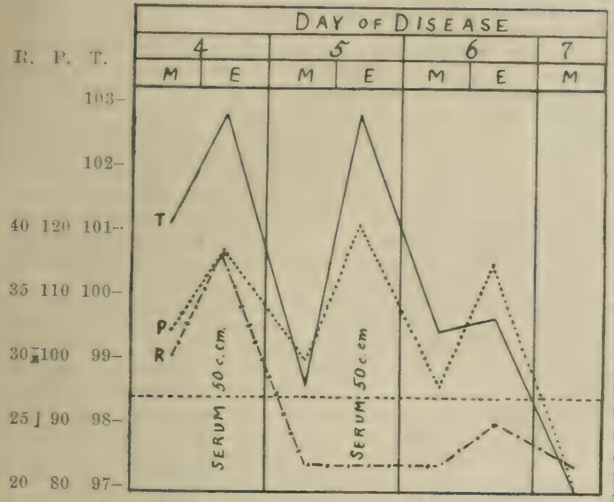
In all patients who recovered a serum reaction appeared, sometimes on the eighth day, more usually on the tenth day after the first administration of serum. In one case it appeared on the sixteenth day, and in another there were two reactions, one on the sixth day and the other on the nineteenth day. The reaction usually consisted of an urticarial rash appearing on the flexor surfaces of the arms and legs, on the chest and abdomen, and occasionally on the face. Joint pains, together with slight rises of temperature, were associated with the urticaria in several instances. Slight hæmorrhage from the bowel, apparently due to an urticarial lesion of the mucous membrane, occurred in one case. The duration of the reactions, modified by injections of pituitrin, varied from two hours to three days. The intense itching of the skin was controlled by a lotion consisting of ac. carbol. ʒi., lot. calaminæ ℥vi.

Evidence of Value of Serum Treatment.

It is well known that lobar pneumonia is a disease in which the prognosis at the outset is uncertain and that many cases recover without any active treatment. The evidence, however, of the value of serum treatment of pneumonia is very strong, especially where the causal organism is the Type 1 pneumococcus. Avery, Chickering, Cole, and Dochez[8] note that the mortality from Type 1 pneumonias before they introduced serum treatment was 25 to 30 per cent.; after the introduction of serum treatment it fell to 7·5 per cent. Nichols,[14] working on the Mexican Border among soldiers found the mortality fall from 39 to 8 per cent. The French observers have noted similar reductions in the case mortality. The fact that the pneumococcus Type 1 is the predominating organism gives a wide range of application to its corresponding serum. The results are better in men than in women, owing probably to the greater incidence in men of Type 1 pneumococcus.

The general impression obtained in treating the comparatively small number of cases in the present series is that the serum is of distinct value. In four desperately ill patients, all admitted before the fourth day of the illness, the effect of the serum was dramatic; one of these cases was complicated by auricular fibrillation but recovered completely. One practically moribund case (not included in the series) of advanced pulmonary tuberculosis complicated by Type 1 pneumonia recovered from the acute attack of pneumonia after 400 c.cm. of serum had been injected intravenously.

CHART 3.



T. W., male, aged 48. Acute lobar pneumonia (Type 1). Showing fall of temperature and pulse after each injection of serum.

Conclusions.

The following general conclusions have been drawn from the results obtained in this series:—

1. The Type 1 antipneumococcal serum has a beneficial effect on pneumonias caused by other types of pneumococci, but not so marked as the effect on Type 1 pneumonias.
2. The best results are obtained when the serum treatment is instituted early in the disease, preferably before the third day.
3. The initial dose of antipneumococcal serum should be 100 c.cm. injected intravenously with the precautions previously mentioned.
4. Serotherapy seems definitely to diminish the incidence of post-pneumonic empyema; in fact, in the present series no such cases occurred. In the case of Type 1 pneumonia, in which horse serum had been injected as a control, empyema developed.

My thanks are due to Dr. W. J. Hadley and Dr. E. H. Colbeck for their suggestions and advice and for permission to publish these notes, and to Dr. S. Roodhouse Gloyne and Dr. D. S. Page, pathologists to the hospital, for carrying out the laboratory investigations and animal inoculations.

Reviews and Notices of Books.

MODERN MEDICAL MONOGRAPHS.

Edited by HUGH MACLEAN, M.D. Aberd., D.Sc., M.R.C.P. Lond., Professor of Medicine and Associate Examiner in Medicine, University of London: Director of Clinical Medicine Unit, St. Thomas's Hospital. London: Constable and Co. 1924.

1. *Modern Diagnosis and Treatment of Syphilis, Chancroid, and Gonorrhœa.* By L. W. HARRISON, D.S.O., M.B., Ch.B., M.R.C.P.E., Brevet Colonel, R.A.M.C., Director of the Venereal Diseases Department, St. Thomas's Hospital: Special Medical Officer for Venereal Diseases, Ministry of Health. Pp. 167. 10*s.* 6*d.*

THE modern Medical Monographs Series has for its object to provide the general practitioner with a short and concise up-to-date account of the position of various subjects of medical interest. This object has been very successfully achieved by Colonel Harrison in this book. It gives a lucid and concise account of syphilis, chancroid, and gonorrhœa in all their manifestations, and with the sections on diagnosis and treatment no fault can be found. While Colonel Harrison has refrained from discussing doubtful points and makes it clear that the views put forward are those of his own school of thought, the book gives no dogmatic impression. To the busy practitioner who cannot overtake the modern literature it should be very useful.

---

2. *Modern Views on the Toxæmias of Pregnancy.* By O. L. V. DE WESSELOW, M.B. Oxon., F.R.C.P., Chemical Pathologist, St. Thomas's Hospital; and J. M. WYATT, M.B. Lond., F.R.C.P., Obstetric Physician in charge of Out-patients at the Hospital. Pp. 99. 7*s.* 6*d.*

THE position taken up by the authors of this volume seems to be substantially as follows. A pregnant woman has albuminuria. If blood and casts are also present in the urine, and she is vomiting, the case is one of "pernicious vomiting," and pregnancy must be terminated. If the albuminuria is accompanied by œdema, the case is either (*a*) "pre-eclampsia," in which case the blood pressure will be high and the nitrogenous constituents of the blood normal, or (*b*) "nephritic toxæmia," which is merely an old nephritis lit up by pregnancy, and hence will show nitrogen retention in the blood and a blood pressure either normal or raised and accompanied by cardiac hypertrophy. Albuminuria without vomiting or œdema is mysterious but unimportant.

If this is not a correct summary of the authors' views we must conclude that it is not easy for a reader of normal intelligence to grasp what they do mean, for we have studied the monograph with the attention due to any work published by Dr. de Wesselow and his colleague. If it is a true summary this monograph fails to fulfil the object outlined by Prof. MacLean, who says in his general introduction: "By reading one of these volumes dealing with a particular problem that interests him, the medical man will know what the present position is." For example, it is misleading to omit to state that there is an important and world-wide body of opinion which holds that the so-called cases of "pernicious" vomiting are nearly all hysterical and are therefore amenable to treatment by suggestion. We feel that the authors are themselves uneasy on this point, for why otherwise do they give full details (pp. 35 and 36) of a scheme of treatment which they then admit to be useless if their diagnosis is correct, and why do they mention urinary changes which have never been considered characteristic of this disease? We feel that it is quite unsafe to label as pre-eclampsia a group of cases which the authors know will in the majority of instances and under any treatment never exhibit a symptom which an obstetrician of 20 years ago would have classified as eclamptic. It is mischievous, because it encourages obstetricians to publish fantastic statistics purporting to show the results of a "prophylactic" treatment of eclampsia, while it tends to lull into complacency medical men who might otherwise be seeking a remedy for this dreadful complication of pregnancy. And, finally, we hold that, if the group which the authors label "nephritic toxæmia" is, as they believe, "merely the expression of the deleterious effect of pregnancy upon a previously existing renal lesion," they have done a disservice to medicine by endeavouring to introduce a new title for the condition.

The names of many authorities are quoted in the book, but no references and no bibliography are given; it is therefore of little value to the specialist. Mistakes such as the classification of raised blood pressure and urinary changes as symptoms, and the incorrect drawing of the graph on p. 50, are details of minor importance. But our deep appreciation of the valuable contributions to our knowledge concerning the chemistry of the blood which have been made in the past by Dr. de Wesselow make us regret the defects of this monograph.

---

3. *Modern Methods in the Diagnosis and Treatment of Pulmonary Tuberculosis.* By R. C. WINGFIELD, M.B., M.R.C.P., Medical Superintendent, Brompton Hospital Sanatorium, Frimley. Pp. 134. 10*s.* 6*d.*

THIS book, like its companion volumes, does not profess to go deeply into the subject, its main object being to give the general practitioner and senior medical student a summary of the most essential aspects of pulmonary tuberculosis. For this reason we do not find the opsonic index mentioned, which is good, but we also find no word about the rate of sedimentation of the erythrocytes, which is a pity. For, though comparatively new, this simple test is generally recognised by continental workers as an invaluable aid to diagnosis, treatment, and prognosis. It is not a test which every general practitioner will carry out, but it is one about which he should know, if it be only to gauge the competency of the consultant, whose advice he seeks, to give the patient the benefits of the most important among the modern advances in medicine. Some of the author's notes on physical examination show him to be an able and experienced clinician, and the following point is one which is as important as it is rare in text-books. "Pay more attention to the healthy than to the diseased areas of the lung. The older the lesion, the more difficult does the correct interpretation of its physical signs become. But the appearance of these in previously apparently normal lung can be taken as evidence of spread of disease." The Brompton tradition is much in evidence. Mouth temperatures, we are told, are as reliable as rectal temperatures; a quarter of a grain of morphine hypodermically is recommended for hæmoptysis and, when the crisis is past, a heavy dose of bromide. The patient is also to be kept on "strict, absolute rest for the next few days." All of which may have support, but it is diametrically opposed to the teaching of other schools, according to which the chief danger of hæmoptysis, except when the loss of blood itself threatens life, is the stagnation of effused blood in the lungs. It is, of course, impossible in a work on pulmonary tuberculosis to please everyone, or, indeed, to please more than a minority, so widely divergent are opinions on the best diagnostic and therapeutic measures. The author has the courage of his convictions and many years of valuable clinical experience in institutions devoted solely to the tuberculous, and however much his fellow-specialists may differ from him, none can deny his competency to speak with authority.

THE STEINACH OPERATION.

The Theory and Practice of the Steinach Operation. By Dr. PETER SCHMIDT. London: William Heinemann (Medical Books), Ltd. 1924. Pp. 150. 7*s.* 6*d.*

THIS book, as well as containing an account of the experimental work upon which Steinach's operation is based, furnishes a report on 100 cases treated by the author. In these reports he has wisely published all the clinical data at his command, obtained from the whole of the patients operated upon, including cases in which no very definite results were obtained as well as those in which the operation appeared to have been highly beneficial. In Dr. Schmidt's opinion the best site for ligature of the vas is near the point of junction with the epididymis. In this he differs from some other authorities who consider a partial epididymectomy to be a preferable proceeding to a vasotomy. After a survey of the clinical reports published in this book it is difficult to maintain an attitude of incredulity towards the results of the operation of vaso-ligature. Even taking into account the effect of suggestion and the possibility of an improvement in general health due to other factors, the changes effected in some of the author's patients appear to have been so striking that one is almost bound to accept the view that they were the result of the operation. The greatest successes appear to have been gained with what may be described in broad terms as cases of premature old age, either partial or total; but apart from these, even such a condition as arteriosclerosis would appear to have been ameliorated. Where, however, the blood pressure is high the author considers it advisable to bring about a preliminary reduction by means of drugs and then to operate, at first, on one side only. If after a lapse of months this should prove insufficient the opposite vas may be ligated. No harmful results have ever been noted by the author, and as a corroboration of this he quotes the experience of Laughlin, in the United States, who after carrying out 2000 vaso-ligations for sterilisation purposes, states that the operation "can cause no harm of any kind to body or mind."

When discussing the theory on which the operation is based Dr. Schmidt shows himself to be an ardent partisan of Steinach's view that the interstitial cells are responsible for the internal secretion of the testis. In the first chapter of his book he furnishes a general critical survey of the experimental work on which this theory is based and does his best to demolish the views of the opposing school who regard the interstitial cells as trophic. It must be remembered, however, that whether this view of the interstitial cells is or is not correct, the work of Steinach still remains, although in the latter case it will be necessary to modify some of his deductions.

This book is one of the best scientific expositions of the subject available for British readers. The large amount of clinical material that it contains should prove of interest to all who are prepared to adopt an unprejudiced attitude towards its subject-matter.

ELEKTROTHERAPIE.

Second edition. By Dr. JOSEF KOWARSCHIK, Primararzt and Director of the Department for Physiotherapy of the Kaiser-Jubiläums-Spital, Vienna. Berlin: Julius Springer. Pp. 312.

THIS text-book on electro-therapeutics is divided into four parts. The first, which is quite short (11 pages), contains definitions and explanations of certain physical terms and units commonly used in medical electricity. Part II. contains 116 pages and is divided into five sections. These deal with the constant current, alternating currents of low frequency and high frequency, diathermy currents, and the various currents from the static machine. The source, production, measurement, and modes of application of these currents are described in separate sections In the third part (71 pages) the author describes the effects caused by the passage of these currents through electrolytes and the human body. The theory of ions is explained, and the migration of ions and the movements of colloids and particles in suspension under the influence of the electric current are described. An account is given of the physiological action of the various currents on motor, sensory, and sympathetic nerves, on the central nervous system, on sense organs and the circulation, and on metabolism. The third part concludes with a section on electro-diagnosis. The fourth part (106 pages) deals with disease and its treatment by electrical methods. The general therapeutic properties of the different currents are described in the first section of this part. In the following 11 sections the diseases suitable for electrical treatment are reviewed, each system of the body being considered in a separate section.

The book is a useful introduction to the principles and practice of medical electricity. The author rightly devotes much space to a consideration of the action of electricity on the body in health, for a knowledge of the physiological effects brought about by electrical currents not only enables us to apply electricity intelligently, but also indicates the lines along which investigation can be most hopefully conducted. Dr. Kowarschik discusses the vexed question of the method of action of the galvanic current when used to treat disease of parts lying beyond the range of entry of ions introduced from the exterior. He acknowledges that the current can generate heat in the tissues, but maintains that the heat is too slight to have any therapeutic value. He thinks the power of the current to cause movement of colloidal particles plays some part, not yet known, in the treatment of disease, although these particles cannot be made to migrate through animal membranes. The therapeutic value of the sinusoidal current is not sufficiently emphasised. The author appears to be cautious in the recommendation of these currents, perhaps in view of fatal results which have followed the application in full-length baths in certain parts of Germany. Static electricity is very briefly considered, and the author does not think much of its therapeutic value. It must be mentioned, however, that the machine installed in his department is extremely small.

The work can be recommended. A noteworthy feature is the number of clear and helpful diagrams.

ELEMENTS OF WATER BACTERIOLOGY.

Fourth edition. By S. C. PRESCOTT, Professor of Industrial Microbiology in the Massachusetts Institute of Technology; and C-E. A. WINSLOW, Professor of Public Health in the Yale School of Medicine. London: Chapman and Hall; New York: John Wiley and Sons, Inc. 1924. Pp. 211. 11*s.* 6*d.*

THIS sound and admirably balanced monograph on Water Bacteriology is now in its twentieth year and, for the present edition, has been largely rewritten. In spite of its long enduring popularity the book is still of a size not beyond the compass of the D.P.H. student, and not too bulky to give the beginner in water examinations an excellent review of the whole subject within a reasonable space of time. A certain number of errors have crept into this edition. For example, Houston's table, quoted on p. 19, lacks column headings, and is, in its present form, absolutely meaningless, and the table on p. 36 is out of place and should be between pages 26 and 27 to which it has reference. The characters of the organisms of the typhoid-colon group, as stated on p. 56, are somewhat inaccurate; *B. lactis aerogenes*, *B. acidi lactici*, and *B. dysenteriæ* (Flexner) all being shown as fermenting dulcitol, which none of them do, and *B. dysenteriæ* (Shiga) being shown as turning milk alkaline, which is a property of an allied and often confused organism which Andrewes has called *B. ambiguus*. In connexion with the differentiation of the coli and aerogenes groups by sugar reactions, the methyl-red and the carbinol tests, there are several contradictions on pp. 57–59. It is a pity that such inaccuracies have been permitted to occur, since the book is one likely to be read as a dogmatic guidance to salvation by the beginner in water bacteriology, rather than as a contribution to the subject from authors of great experience for those whose life's occupation lies in this type of work. But the beginner should read it with much profit, if he carries away with him nothing more than the recognition that "In sanitary water examination . . . the factors involved are so complex, and the evidence necessarily so indirect, that the process of reasoning much more resembles a doctor's diagnosis than an engineering test."

ANNALS OF MEDICAL HISTORY.

Vol. VI. No. 2. June, 1924. Philadelphia: Paul B. Hoeber. $2.50.

THE principal articles in this number are biographical—namely, papers upon Sir William Bowman, Carl Weigert, Spallanzani, and Sir William Buttes, who was physician to Henry VIII. We think that the author of this paper, Dr. T. N. Toomey, is in error when he translates the commencement of Henry VIII.'s grant to Buttes by the words, "King by all, &c.," for though he only gives the two first words of the preamble—namely, "Rex omnibus, &c.," the beginning was probably "Rex omnibus ad quos presentes litere pervenerint. . . ." Also, in the last line of Buttes's epitaph Dr. Toomey transcribes "Mors mihi nunc lucum vitaque Christus erit," and translates, "Now that I am dead, Christ will be to me refreshment and life"; it is surely obvious that "lucum" should read "lucrum," and equally obvious that the line is simply a poetical rendering of St. Paul's remark (Phil. i. 21) as given in the Vulgate, "Mihi enim vivere Christus est, et mori lucrum." Apart from these little oversights the paper is good, and Dr. Toomey has been at much trouble to consult original sources of information. Dr. Francis Packard, the editor, gives his readers an interesting paper upon References to Venereal Diseases, in which, with the art of a practised writer, he arrests attention at the outset by a quotation which has nothing to do with syphilis. The best paper in the number, however, is that by Dr. John Ruhrah, entitled James Atkinson and his Medical Bibliography, a scarce and amusing book and a great favourite of Osler. We share Dr. Ruhrah's wonder that it has never been reprinted, but are sincerely grateful to him for having given us a generous number of quotations from it. Bibliography pure and simple is an arid form of literature; as annotated by such men as Atkinson it is most stimulating.

BRITISH WINES AND CORDIALS.

THE Ministry of Health has recently published No. 24 of its "Reports on Public Health and Medical Subjects" (1*s.* 6*d.*), dealing with the composition of commoner British wines and cordials (alcoholic and non-alcoholic). Dr. G. C. Hancock, one of the Ministry's medical officers, is responsible for Part I., which deals with the historical and technical side of the industry, while the much larger Part II., contributed by the Government Chemist, consists of a classified summary of the results of the analyses of some 360 samples. The composition of these beverages formed the subject of a special inquiry by the Local Government Board, which was begun in 1913, but owing to interruption by the war it has only just been completed.

Many of these beverages, although not specifically described as temperance drinks, are not uncommonly regarded as such, and, roughly speaking, they may be divided into two classes—namely, those which contain alcohol and those which really are temperance drinks. Strictly speaking, the term "wine" should be applied only to the former, since wine in its broadest sense is the fermented expressed juice of any fruit, though the term is generally understood to apply to the juice of the grape. The term "British wine" has, however, been applied to a number of beverages manufactured in the British Isles, some of which contain alcohol produced in part by the fermentation of fresh and dried fruits, whilst others consist for the most part of sugar solutions flavoured with fruit juices, fruit essences, and other flavouring agents, and contain no alcohol or only an amount not exceeding 2 per cent. of proof spirit, as permitted by the Excise authorities. Fermented wines are usually sold without any special indication that they contain alcohol, but temperance drinks are almost invariably described as "non-alcoholic," "non-excisable," or "unfermented." The yearly consumption of British wines and cordials is difficult to estimate. The annual output of fermented British wines probably does not exceed 2 million gallons. The manufacturers of these wines, with few exceptions, use preservatives in some form, those most commonly used in fermented beverages being sulphurous acid and sulphites. Salicylic acid, although the most favoured preservative for temperance wines and cordials, does not appear to be extensively used in alcoholic beverages. For the sake of convenience, the preservatives and alcoholic content of both unfermented and fermented wines have been tabulated, and the analyses are shown in the following table :—

—	Samples of—	
	Fermented British wines.	British unfermented wines and cordials.
Preservatives . .	Nearly all contained some.	Very commonly added; salicylic or sulphites either alone or together are the most general. Neither beta-naphthol nor formaldehyde found.
Sulphurous acid and sulphites.	14 % contained over 1·8 gr. per pint. 18·6 % contained 0·9 to 1·8 gr. per pint. Maximum (orange wine) 3·78 gr.	Present in traces in nearly all. In 29 samples it exceeded 0·9 gr. per pint; in 5, 1·8 gr. Maximum 3·52 gr. per pint.
Salicylic acid . .	Not extensively used; 10 % contained amounts varying from 0·25 to 1·57 gr. per pint.	50 % contained from a trace to 11·9 gr. per pint.
Boric acid . .	5 % contained from 1·38 to 2·98 gr. per pint.	Present in 18 samples, ranging from 1 to 14·3 gr. per pint, and in all but 4 cases in addition to salicylic or sulphurous acids.
Benzoic acid . .	—	Found in 2 samples: 4·7 and 10·6 gr. per pint.
Proof spirit . .	May contain from 14·8 to 28 %. Ginger wine from 10·9 to 27 %.	Usually under 2 %, but 2 samples contained 23 %, though marked "non-alcoholic."
Saccharin . .	—	Found in 10 out of 44 samples of wine, and in 7 out of 98 samples of cordials. The amounts ranged from a trace to 4·6 gr. per pint.

Alcohol, either in the form of grain or wine spirit, is an ingredient occasionally added to fermented wines, but its use for the most part appears to be limited to certain manufacturers of ginger wine who export to the British colonies. British fermented wines may contain from 20–28 per cent. of proof spirit and therefore do not need to be fortified. Of the vegetable acids, tartaric and citric are sometimes added, usually before fermentation or in the preparation of the syrup.

Unfermented British wines are sold under similar names to those given to fermented wines but in larger variety. They are manufactured in much the same way and contain similar ingredients, the chief difference between a wine and a cordial being the density of the syrup which forms the basis of both; in the case of wines, the syrup usually contains from 1·5 to 3 lb. of sugar to the gallon, while in cordials it runs from 3 to 6 lb. to the gallon.

In addition to its sweetening power, some manufacturers are aware of the antiseptic value of saccharin, and, since for equal sweetening power, this substance is in normal times about half the price of sugar, advantage in a commercial sense is effected by its use. The use of artificial colouring matter is practised to a greater degree in the colouring of temperance drinks than in the colouring of alcoholic drinks, and 30 per cent. of the samples analysed by the Government chemist were found to contain coal-tar (aniline dyes) in very minute amounts. As regards the use of saccharin, it should, of course, be remembered that this substance has no relation chemically to sugar and is not a food, and its use in food is prohibited in the United States save in respect of certain drugs and classified foods containing this substance which may be required for the mitigation or cure of disease (Food Decision No. 142, United States Department of Agriculture). Its use in British wines and cordials has been shown to be limited for the most part to some of the non-alcoholic wines and cordials. This statement does not apply to the manufacture of sweet mineral waters in which saccharin appears to be much more commonly employed. Most manufacturers are, however, able to do without saccharin, and it is clearly not necessary in the preparation of these beverages. An expert American committee who reported on the use of saccharin summarised their conclusions as follows: (1) Saccharin in small quantities (4·6 gr. per day or less) added to food is without deleterious or poisonous action, (2) in larger quantities (over 4·6 gr. per day and especially above 15·5 gr. daily) if taken for considerable periods of time, especially after months, is liable to induce disturbances of digestion.

Coming now to the use of salicylic acid, which is the most commonly employed preserving agent in temperance drinks, the author states it is a powerful drug, and, like sulphurous acid, has the quality of inhibiting especially the growth of moulds and those organisms which cause fermentation in fruit preparations. Williams and Starling have found that it retards gastric digestion but has practically no effect on pancreatic juices; on the heart it exercises a depressing effect. Within recent years feeding experiments with this preservative on human beings have been conducted by the U.S. Bureau of Chemistry (Bulletin No. 84, Part 2, 758–9). The conclusions which were drawn from the study of the clinical and medical history of the men under observation are summarised as follows :—

> "The final conclusion in this matter is that the unenviable position which salicylic acid has heretofore held among preservatives, in being regarded as the most injurious of all, is to a certain extent undeserved. Like other ordinary preservatives, it is not one which can be classed as a poison in the usual sense of the word. When used as a medicine in many cases of derangement of health it is, like the other chemical preservatives, often highly beneficial when properly prescribed by a competent physician. It is when used in the food at first an apparent stimulant, increasing the absorption and solubility of the common food elements from the alimentary canal. It soon, however, loses its stimulating properties and becomes a depressant, tending to break down the tissues of the body more rapidly than they are built up. It disturbs the metabolic processes, in most cases producing conditions which are not normal and which, apparently, are not beneficial. It has a tendency to diminish the weight of the body and to produce a feeling of discomfort and 'malaise,' which, while not marked, is distinctly indicative of injury. In some cases these symptoms of 'malaise' approach illness, and, while not always diagnostic, are sufficiently common to point unmistakably to the salicylic acid as their origin. It places upon the excretory organs, especially the kidneys, an additional burden which they are not able to bear, and which cannot possibly result in any good, but, on the contrary, must necessarily finally result in injury, though perhaps with the use of very small quantities of the preservative these organs would continue to perform their function for many years before finally breaking down."

The Departmental Committee, appointed in 1899 to inquire into the use of preservatives and colouring matters in food, recommended that the quantity of salicylic acid permissible in liquids should not exceed 1 gr. per pint. Of the temperance wines and cordials examined by the Government Chemist 50 per cent. contained salicylic acid. The table below shows the number of samples which exceeded the 1 gr. limit recommended by the Departmental Committee.

Salicylic acid.			No. of samples.
Exceeding 1 gr. but not exceeding 3 gr.		..	28
,, 3 gr. ,, ,, 7 gr.		..	21
,, 7 gr. ,, ,, 12 gr.		..	9
Total	..	..	58

As the question of preservatives and colouring matters in foods is again under consideration by a Departmental Committee appointed by the Minister, Dr. Hancock states that he has refrained from making any specific recommendations in the matter.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

XVIII.—LIBEL AND SLANDER.

BY HUGH WOODS, M.D.,
GENERAL SECRETARY, LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

> "Where it concerns himself, who's angry at a slander makes it true."—BEN JONSON, *Catiline*, Act III., Scene i.

EVERY medical practitioner ought to have a sound elementary knowledge of the law of libel and slander, for not only is he, by the nature of his profession, much exposed to libel and slander and very liable to serious damage from them, but he also runs serious risk, in the course of his professional duties, of himself libelling or slandering others, or of giving opportunities for accusations and claims for damages against him on the ground of alleged libel or slander. Before discussing the subject in its special reference to medical practice, I will therefore briefly set out a few elementary principles with which every practitioner ought to be familiar.

Elementary Principles.

Defamatory Words.—Words which produce, in any given case, appreciable injury to the reputation of another are called defamatory, and defamatory words, if false, are actionable. False defamatory words, if written and published, constitute a libel; if spoken, a slander. False words which by their nature evidently must damage the reputation are actionable without proof that any particular damage has followed, otherwise it must be proved that some appreciable injury has in fact followed from the words spoken or written. Such evidence of "special damage" is not required when the words complained of were spoken of the plaintiff in the way of his profession or trade or an office of public trust, as it is assumed that disparaging words will under these circumstances cause injury even if specific instances of damage are not in evidence. In order to judge whether certain words are defamatory or not it must be considered whether the nature of the words is such that it must be presumed that they would seriously injure the reputation of the person referred to as being disparaging or tending to bring into ridicule and contempt, when written; or when spoken, as charging with the commission of a crime, with having a contagious disorder, with unchastity or adultery in the case of a woman, or as disparaging the person in his or her trade or profession. When it cannot be presumed that the words must cause appreciable injury it is necessary to prove that they have in fact produced injury to the patient's reputation. The presumption that words are defamatory arises much more readily in cases of libel than in cases of slander, since for several reasons they are more likely to cause injury when written than when merely spoken.

Malice.—It is not necessary to prove that there was any wrong intention or motive in the use of defamatory words unless the words are privileged by reason of the occasion on which they were employed. Words, if false and defamatory, are actionable (when not privileged) even though published with an honest belief in their truth or accidentally or inadvertently. Absence of malice may, however, be pleaded in mitigation of damages. When the judge has ruled that the occasion was privileged in an action for defamation, the plaintiff has to prove malice. The question whether there was malice or not is for the jury, unless the judge rules that there is no evidence of malice to go to the jury. Malice in law is any indirect motive other than a sense of duty, and not only feeling against the plaintiff. If malice is proved, the privilege attaching to the occasion, unless it be absolute, is lost. The fact that the defendant at the time of the publication of the defamatory words knew that they were false is clear evidence of malice, but even if the defendant honestly believed in the truth of what he said, and was acting under a sense of duty on a privileged occasion, still the words used and the manner and mode of their publication may afford evidence of malice. Where the language used is much too violent for the occasion and circumstances to which it is applied, or utterly beyond and disproportionate to the facts, or where improper motives are unnecessarily imputed, there is evidence of malice to go to the jury.

Privileged Occasions.—An occasion is privileged when the circumstances under which defamatory words were written, or spoken, were such as to make it right that the writer or speaker should honestly state what he honestly believes of the character of another, and to speak his mind fully and freely about him. Privileged occasions are of two kinds: those absolutely privileged, and those in which the privilege is qualified. Privilege is absolute in the case of words spoken by a judge on the bench, by a witness in the witness-box, words spoken in Parliament, &c., and even if the words were spoken falsely, knowingly, and with express malice, they are not actionable. Where the interests of the public do not demand that the speaker should be freed from all responsibility, the privilege is qualified, and not absolute, and damages can be recovered in spite of privilege if it can be proved that the words were not used in good faith, but that the privileged occasion was made use of for the purpose of wilfully and knowingly defaming another. It is for the judge alone to decide whether or not a communication is, or is not, privileged by reason of the occasion. If the occasion is absolutely privileged judgment will at once be given for the defendant. If the judge decides that the occasion is one of qualified privilege only, and the plaintiff puts forward any evidence of malice sufficient to go to the jury, it is then a question for the jury whether or not the defendant was actuated by malicious motives in writing or speaking the defamatory words, and if the jury find that he was so actuated the protection of privilege is lost.

Publication.—Publication is the communication of the defamatory words to some person or persons other than the person defamed. In civil proceedings communication of the words to the person defamed only is not publication. It cannot damage his reputation. When the words are such as obviously would provoke to a breach of the peace, criminal proceedings can be successfully taken when they are communicated only to the person defamed, provided the words are written and not merely spoken. Criminal proceedings cannot be taken for slander.

Justification.—It is a complete defence to any action for libel or slander if the truth of the defamatory words, on which the action is founded, is proved. In a criminal trial for libel this defence is not sufficient. The defendant must, however, prove that the words used were true in substance and in fact, and not merely that they were partly true. The onus of proving that the defamatory words were true rests on the defendant, and, failing such proof, they are assumed to be false. If the jury find that the words were true in substance and in fact they must find for the defendant, even though the words were used maliciously; if they find that the words were false they must find for the plaintiff, even though the defendant in their opinion honestly and reasonably believed that the words were true when he uttered them.

Medical Practitioner as Plaintiff.

To have and to maintain good reputation is a matter of very serious concern to medical practitioners, and they ought to give thoughtful and careful attention to the best means of protecting it against those who wantonly or wickedly seek to detract from it. Doctors are a frequent subject of gossip, but, when it tends to damage them, they should remember that it is not always defamatory, and that they often derive substantial benefit from it. Ordinary foolish gossip should be altogether ignored, even though it be irritating and unfair, since by dealing with it seriously as a slander, wide publicity may be given to it, and people may even be led to infer that it is founded on some substantial basis when it is nothing more than mere irresponsible chatter.

Spiteful persons frequently write letters to medical practitioners accusing them of incompetence, malpraxis, negligence, or unprofessional conduct, when they are annoyed by being pressed for payment of fees due for medical attendance, by refusal of untrue certificates in support of unjustified claims, by reprimands for recklessly giving unnecessary trouble, or by the expression of opinions with which they disagree or which are distasteful to them. A medical practitioner, on receipt of such a letter, sometimes answers angrily, demanding withdrawal and apology, with threats of legal proceedings. As there has been no publication of the libel, the writer can safely, and often does, reply reiterating his accusations and adding to them. When the practitioner proceeds to carry out his threats he learns to his disgust that he has no grounds for action, and that he has simply given the writer the gratification of knowing that his words have caused the annoyance they were intended to cause. Such letters should either be treated with silent contempt, or the writer should be told that his accusations are unfounded and that any publication of them to others will be appropriately dealt with. When letters of the kind are written by relatives of deceased patients, distressed by their loss, and unreasonably blaming the doctor for his lack of success in his treatment, they should be answered firmly but sympathetically, and the unreasonableness of the accusations should be explained in a kindly spirit. In this way honest but foolish fancies can often be quite satisfactorily dispelled.

Medical practitioners should, if possible, avoid bringing actions for libel or slander. They often give world-wide publicity to false charges which would not otherwise have reached more than very few, and would have received little credence. It is very unwise to bring such actions when there is risk of failure owing to technical difficulties, apart from the truth or falsehood of the defamatory statements. People will often overlook the real reasons for the failure of an action, and regard it as a justification of the libel or slander complained of. The occasions on which doctors are libelled or slandered are very frequently more or less privileged, and proof of legal malice presents many pitfalls. Practitioners who are medical officers to public bodies, or panel doctors, are very liable to false charges made to the authorities whose duty it is to investigate such charges, and in these cases there is seldom clear enough evidence of malice to deprive the complainant of the protection of privilege. Members of boards of guardians, of local councils, &c., often make slanderous statements about medical officers, which are reported in newspapers. The slanderers, and the newspapers giving a correct report of their remarks, can plead privilege, but a newspaper which publishes the defamatory statements must, if requested, publish a denial of the defamatory statements, or it will render itself responsible for them. Such public contradiction is often the only remedy open to the practitioner who has been unjustly accused.

When a really grave libel on a medical practitioner is openly published it should be promptly dealt with, and failing an unreserved withdrawal and apology with publicity equal to that of the libel, legal proceedings should be taken, and full public vindication established. Unfortunately, the originators of intolerable libels or slanders are, more often than not, impecunious, and careless what damages may be awarded against them because the plaintiff cannot take from them what they do not possess. In such cases it may nevertheless be necessary to take legal proceedings so as to obtain an injunction restraining the defendant from continuing to publish the libels or slanders, and a disregard of the injunction can then be punished by imprisonment. Occasionally a medical practitioner receives a letter which constitutes a criminal libel although not published to others than himself—for instance, one accusing him falsely of criminally inducing abortion. In such a case he should not shrink from prosecuting, bearing in mind that an unfavourable construction might be put upon his inaction if subsequently he should be prosecuted for the alleged offence.

Medical Practitioner as Defendant.

A statement that a person is suffering from disease is often defamatory, and as the most talented practitioner is liable to error in diagnosis it may be false. The result of a statement by a doctor that a patient is suffering from tuberculosis or cancer may lead to his being dismissed from his employment if made to a third person, and the doctor may be liable for the damage resulting to the patient. Medical certificates should therefore be given to the patient himself and not to an employer, or friendly society, without the express authority of the patient. To talk about the ailments of patients to others is, of course, wrong and dangerous, and should be strictly avoided. Even though the protection of privilege may be available in the case of medical certificates or reports to employers or friendly societies, or the like, there is still a certain amount of risk which it is discreet to avoid. If the truth of the statements made can be proved no damages can be recovered, but legal proof that a person is suffering from a particular disease is often extremely difficult, even when the diagnosis is in fact quite accurate. When there is a statutory duty to report that a patient is suffering from an infectious or other disease, it is sufficient to prove that proper care was taken in arriving at a diagnosis and that it was honestly stated according to the best of the practitioner's knowledge and belief. When a doctor violates the recognised rule of professional secrecy, and fails to prove the truth of damaging statements made by him about a patient, vindictive damages are not unlikely to be awarded against him.

Libel or slander of a fellow practitioner is suspected much more often than it occurs, but it is unfortunately not unknown. Alleged slander of doctors by doctors usually turns out on inquiry to have arisen from false reports by patients of what has been said to them, or sometimes from deliberately false statements by them. When a medical practitioner disagrees with the advice or treatment of another, he should weigh his words carefully, and not attribute ignorance, incompetence, or malpraxis to a doctor who has honestly formed a different opinion, even if he has been quite wrong in his views or his treatment. It may be his duty to express definite disapproval of the advice or treatment given, but, without clear proof, he ought not to attribute negligence, want of skill, or wrong doing to a patient's previous medical adviser, and still less to make unfair or captious criticisms.

THE LANCET.

LONDON: SATURDAY, OCTOBER 4, 1924.

THE PRINCIPLES OF SUCCESS IN MEDICINE.

DURING the past week addresses have been delivered at the opening of the winter session in many of the London schools of medicine. The introductory habit appears to be nearly confined to London, for most of the large provincial schools plunge straight into their work without beginning to commence, and the stimulating address is not appropriate to North Britain, where the temperament of the medical student needs no stimulus in order to count on success. The addresses have in some cases been delivered by past members of the school whose success in one of the manifold fields of medical endeavour is rightly used as a spur to those just starting on their course. In other cases the school has invited an outsider whom wide experience has entitled to speak worthily on medical aims. All the addresses which we reproduce in abridged form in this issue of THE LANCET put into other words the message of the Apostle to the Gentiles, to keep in mind whatever is true, whatever is worthy, whatever is just, whatever is pure, whatever is attractive: advice which contains the germ of psychotherapy no doubt prompted by the medical companion of his journeyings. Success, in the mouths of the several speakers, implied many different things; personal and professional in the first instance, overflowing into communal and social channels and even affecting the welfare of the race. Sir ISAMBARD OWEN exhorted his hearers to work for a real science of therapeutics based upon exact observation, an aim in the pursuit of which he had given some of the busiest years of his life. Dr. CHARLES PORTER'S message to his hearers is epitomised in the transposition of a word in the title of his address; asked to speak on "Some Aspects of Preventive Medicine" he chose to speak on "Some Preventive Aspects of Medicine," in order to impress on his hearers the view that preventive medicine is not a subject for specialists, but for every man and woman entering upon the practice of medicine. His address might have been directed to refute Mr. BELLOC'S gibe at hygiene in our happier age—"for now we know both how to make them sick and keep them so." Sir HUMPHRY ROLLESTON, in handing awards to prize-winners, was careful to point out how the student who matures slowly may eventually excel his prize-winning contemporary of hospital days. Some ambition and much patience would go far to supplement the moderate degree of ability required for those who set out to attempt consulting practice. Mr. H. J. WARING spoke of the organisation of medical practice, giving as his conviction that under a proper grouping it would be right and possible to hand over to the medical profession the whole responsibility for the health of the people. The medical man, he was satisfied, could play a larger part than he was now playing in public affairs, imperial and local. Sir DAVID FERRIER, whose brilliant deductions were largely responsible for opening the sealed book of brain localisation, nevertheless pleaded that with all the increased diagnostic facilities with which scientific method had now endowed us, there should be no atrophy of the trained faculty of the skilled practitioner, no disuse of the unaided tactus eruditus. The factor of success surpassing all others in importance is, as he expressed it, a thorough knowledge of work, and all those who have followed the steps by which the speaker attained to certainty will admit his right to speak on this theme. To those who may be inclined to doubt whether the special direction of medicine that interests them is likely to bring success in its train we commend a consideration of the letter in our correspondence columns signed by one who conceals over an unjust pseudonym much experience in the Services. Two now famous directors-general started their careers as bacteriologists, and it is impossible to forecast from what branch of medical study will be chosen the administrator of 30 years hence. The message of other opening addresses not noticed in this brief summary was addressed to the needs and interests of the particular student rather than to a wider circle, but we must not overlook the remark of the Dean of the Middlesex Hospital in speaking of the great part played by that hospital in bringing home to the people of London the importance of the scientific side of medical work. At the London School of Medicine for Women the Dean's address was of a domestic character in view of the jubilee celebration to take place towards the end of the present month.

HEALTH LEGISLATION IN PROSPECT AND RETROSPECT.

NEITHER the present short session nor the coming autumn session of Parliament, likely to be occupied with high affairs of State, may be able to devote much attention to health measures, but there are several Bills on these domestic topics sufficiently mature to be ready to pass into law. The House of Lords has already approved the Therapeutic Substances Bill for regulating the manufacture, sale, and importation of vaccines, sera, and other substances, including salvarsan and insulin. The House of Commons has passed the Public Health (Scotland) Amendment Bill to allow local authorities to assist persons who could not otherwise afford it to obtain insulin treatment. Other Government Bills in the list are the Factories Bill and the Lead Paint (Protection against Poisoning) Bill, both prepared by the Home Office, the Board of Trade's Bill as to sale of bread, and the Mines Department's Coal Mines (Washing and Drying Accommodation) Bill. Of these the Factories Bill is believed to have the best chance. Part of it is mere consolidation of existing law, part is extension and amendment. There is a good deal of confusion to be cleared up in factory and workshop legislation. Last March an Order was made as to first-aid equipment at quarries and pit-banks. It was an excellent Order, but its statutory origin was obscure. Those who were curious to track down the statutory authority for the Order found it hidden in a Workmen's Compensation Act; and those who wondered why that particular provision applied to quarries found the reason in the legal definition of a quarry as a "non-textile factory." All these distinctions between a textile and a non-textile factory and between a factory and a workshop will be removed if the new Bill becomes law. Various matters at present covered piecemeal by Welfare Orders and Departmental Regulations will be dealt with comprehensively by statute. Another proposed change is to hand over to factory inspectors (in place of local sanitary authorities) the enforcement of provisions relating to cleanliness, overcrowding, ventilation, and sanitary conditions.

When the two Houses rose in August the chief achievement of the year in health legislation was the alteration of the law of workmen's compensation in respect of silicosis. The National Health Insurance (Cost of Medical Benefit) Act closed a controversy in which the approved societies had taken a vigorous part. The consolidating National Health Insurance Act is a boon to all concerned. Its 150 pages contain in a single and well-constructed code the whole of the permanent law, and it is understood that corresponding codes of national health insurance regulations will be issued at the end of the year when the Act takes effect. The consolidating Bills relating to housing and town planning have yet to receive the Royal Assent. Many other measures directly or indirectly concerned with health and social welfare have had their careers checked. The Bills as to adoption of children, guardianship of infants, and legitimacy are examples. Colonel FREMANTLE's useful Births and Deaths Registration Bill is not yet law. Lieut.-Commander KENWORTHY'S Dogs' Protection Bill (to restrict vivisection) had its counterpart in the House of Lords, where Lord BANBURY of Southam was once more heard upon a topic he has made his own. Lord BANBURY'S Bill was successfully opposed by Lord KNUTSFORD in a debate in which the Lord Chancellor declared that the Government considered the Bill would put an end to essential research, and Lord PARMOOR reported the unanimous opinion of the Medical Research Council to the same effect. One Bill which has not yet had as much consideration as it deserves is the Smoke Abatement Bill, which the House of Lords briefly discussed last July. A House of Commons measure for which much might have been said was Mr. WELLS's Public Health Acts (Amendment) Bill "to incorporate in one Act certain provisions relating to public health and local government contained in local Acts." To bring all local authorities into line with the most advanced municipalities in health matters is a most laudable ambition. Unfortunately, in the present congestion of Parliamentary time, health standards, in so far as they can be advanced by legislation, make better progress by local than by public Act.

◆

THE AFTER-HISTORY OF BREAST-CANCER OPERATIONS.

THE gradual evolution and perfection of surgical therapy in general has accustomed us to expect a high percentage of cures in most diseases where such treatment is undertaken, but there must be one reservation in making such a statement. In malignant disease an equally high proportion of permanently good results can by no means be claimed in spite of the vast amount of care, thought, and effort which has been expended upon the elaboration of technique devised to eradicate it. The natural disappointment which has followed the failure of sustained attempts to ensure the same measure of success in cancer operations as is obtained in other departments of surgery has expressed itself of late in a certain pessimism to be discerned in the writings of surgeons engaged in the treatment of the various manifestations of this malady. There has grown up an atmosphere of diffidence and uncertainty as to the propriety of performing some operations which have been regarded until lately as essential proceedings if cure is to be obtained, a questioning of the advisability of attempting to expel the disease by such extensive removals as have been in vogue. In the case of cancer of the breast there has arisen a vague feeling, scarcely amounting to a definite opinion, that the end-results of modern operations have not been commensurate with the alterations and supposed betterment of technique employed. It is easily understood why such contentions should be put forward. Every surgeon is aware of a number of recurrences which have taken place in his own practice after what have appeared to be most satisfactory procedures in the light of present-day surgical knowledge. The general practitioner can tell of early cases where, in spite of a thorough local removal, the patient has succumbed subsequently to secondary growths in other parts of the body. These tragic results, where large operations have failed to avert the fatal issue, make deep and lasting impressions upon the practitioner's or surgeon's mind. They call forth doubts about previously unquestioned beliefs in the advisability of and necessity for the modern extensive operative procedures. In these circumstances, the inquiry into cancer of the breast, initiated by the Departmental Committee on Cancer of the Ministry of Health, is of very considerable value. The investigation was carried out by Dr. JANET E. LANE-CLAYPON. The literature of the last 50 or 60 years from nearly all European countries and from America has been laboriously submitted to modern statistical methods of research. Never before has such a comprehensive review of this subject been undertaken, and the care which has been bestowed to avoid errors in making deductions from the enormous amount of material at the disposal of the author invest the results arrived at with an exceptional degree of reliability. In all, the case reports of 25,410 patients came under consideration, and of these just under 20,000 were available for the study of end-results. The report is arranged under three separate sections, which deal with the operation and its results, the clinical condition of the patient, and the ætiology.

The question whether the "complete" operation gives better results than those claimed by the older surgeons who practised the "incomplete" method appears to be settled in the affirmative. All the statistics, even when critically analysed, seem to show that more patients survive any given point of time after operation when it has been of the modern "complete" type. Nor does there appear to be any ground for thinking that cancer cells are disseminated more easily by the bigger operation. It is admitted that, in spite of surgical treatment, a deplorably large percentage of operated patients subsequently die of metastases. Have these women gained anything by submitting to operation? Has the time of death been hastened, postponed, or unaffected? It is not easy to reach a decisive answer to these questions for the following reasons. Unfortunately for Dr. LANE-CLAYPON, most authors have taken the unduly short period of three years as the crucial interval after operation on which to assess their results, and she has thus been forced to use this period as a basis of calculation of average results. The difficulties of following up cases over a long period of years are great, but since not a few patients survive for three years and yet succumb to recurrence many years later, it would seem worth while for surgeons to extend their basis of calculation to five if not to ten years survival after operation. We understand that the inquiry which is now being made by the Medical Society of London will cover the longer periods of survival. In considering such a problem as the curability of cancer, and the relative values of partial and complete operations, a more severe test than three years would seem necessary, especially since the average expectation of life after the onset of cancer of the breast, when the disease runs its own course, is estimated at three and a half years. Bearing these limitations in mind, the outcome of Dr. LANE CLAYPON'S inquiry remains of great interest. She concludes that after the complete operation 50 per cent. of patients pass the three-year period, and 33 per cent. will be alive at the end of five years. Making allowances for the natural death-rate of persons at the cancer age and other corrections, the deduction is arrived at that the mean duration of life from the "complete" operation is five years eight months. Now, on the average, patients do not come to operation until one year after they are aware of the onset of the disease. Hence with the complete operation the expectation of life is six years eight months, so that the result of operation is to prolong life by more than three years of actual time. If we turn to patients operated upon in the early and most favourable stages of the disease, the gain is seen to be much greater, for they live on an average ten years longer than the operated cases. With regard to the use of X rays and radium as auxiliary measures to surgery, the author declares that practice has not been sufficiently standardised for data which lend themselves to statistical inquiry to be available.

The whole report is full of interesting facts which emerge from the inquiry. Thus the belief that cancer in young people follows a more malignant course is shown to be erroneous, and numerous other questionable points which have long been in doubt are settled. The active surgeon must feel gratification in the demonstration that, though his results in this disease fall far short of perfection, yet he is the means of prolonging life for considerable periods and certainly ameliorates the unhappy lot of those unfortunate women who inevitably fall victims to the late manifestations of it. It is clearly brought out also that the prognosis is incomparably better when the patients apply early for surgical relief. The hope for improvement in the future lies in this direction rather than in further extension of the operation, which seems to have been pushed to its practical limits.

The Services.

CIVIL CONSULTANTS TO THE ROYAL NAVY.

THE following Civil Consultants to the Royal Navy have been recently appointed by the Admiralty:—Sir Humphry D. Rolleston to be Consulting Physician; Mr. Arthur Edmunds to be Consulting Surgeon; Dr. C. Hubert Bond to be Consultant in Mental and Neurological Diseases.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. R. H. St. B. E. Hughes is placed on the Retd. List with the rank of Surg. Capt.

C. H. Savory (late Tempy. Surg. Lt. R.N.) to be Surg.-Lt.

E. J. K. Weeks to be Surg. Lt.

TERRITORIAL ARMY (R.A.M.C.).

Col. J. Clay, T.D., K.H.S., resigns his commn. and retains the rank of Col. with permission to wear the prescribed uniform.

Lt.-Col. J. M. Gover, from R.A.M.C., T.A., to be Col. and Assistant Director of Medical Services, 50th (Northern) Division, T.A., vice Col. J. Clay.

Capt. W. E. Hodgins resigns his commn. on appt. to the R.A.F.

G. H. R. Gibson (late Canadian Army Medical Corps) to be Capt.

Capt. J. Robertson (late R.A.M.C., S.R.) to be Capt.

Surg. Lt. N. Braithwaite (late Royal Navy) to be Lt.

D. F. Hocker to be Lt.

ROYAL AIR FORCE.

Flight Lt. E. D. D. Dickson and Flying Officer J. G. Russell are granted permanent commns.

Annotations.

"Ne quid nimis."

VOLUNTARY BOARDERS IN MENTAL HOSPITALS.

THE story was told many years ago by a medical officer of one of the large mental hospitals in Scotland that one day he was standing at the main entrance of the hospital in the company of a head attendant who had grown grey in the service of the institution. As they were chatting together and looking down the carriage drive, a man carrying a portmanteau was seen to approach. The head attendant, who was rather proud of his clinical sagacity, remarked: "Here comes a new patient, and he must be very bad indeed as he comes by himself." The speaker may have intended his remarks to have been taken as a sample of pawky humour, yet they were no doubt in sympathy with current trained opinion and would be echoed by the ordinary layman at the present time. The average man would say that a patient must be very insane indeed if he were of his own free will to seek admission to a mental hospital. Yet what are the facts? Every year large numbers of voluntary boarders apply for admission, and there are mental hospitals in England and in Scotland where those received in this way actually exceed in number those that are certified. In England voluntary boarders can be received only in registered hospitals and licensed houses. Bethlem Royal Hospital and Holloway Sanatorium are examples of the former, and "licensed house" is but another name for "private asylum." The large mental hospitals managed by committees of county councils or county borough councils are not permitted by law to admit voluntary patients. It is pleasant, however, to be able to record that there are two exceptions to this statement. A special Act of Parliament empowers the Maudsley Hospital, which was built by the generosity of the late Dr. Henry Maudsley and is under the control of the London County Council, to receive voluntary boarders only. Just recently the Royal Assent has been given to the City of London (Various Powers) Act, 1924, under which voluntary boarders can be received at the City of London Mental Hospital, Dartford. By the same statute the words "mental hospital" replace the word "asylum" in the official title of the institution.

SUBOCCIPITAL PUNCTURE IN MENINGITIS.

IN a recent number of the *Münchener Medizinische Wochenschrift* Dr. Adolf Hartwich, assistant in the Medical Clinic of Halle University, reviews the literature and records his experience of suboccipital puncture for removal of fluid from the cisterna magna in meningitis. Apart from 81 occasions on which he has employed the method for diagnosis he has recently used suboccipital puncture with success in two cases of cerebro-spinal fever. The first patient was a girl, aged 12, in whom suboccipital puncture was performed 13 times in the course of 25 days, 20 c.cm. of anti-meningococcus serum being injected on each occasion after removal of 30 c.cm. of cerebrospinal fluid. The injections were well borne, although the patient complained of headache regularly after each injection. Recovery took place in five weeks. On several occasions lumbar and suboccipital punctures were carried out at the same time, and comparative observations were made of the globulin reactions, the cellular content, and the pressure of the column of cerebro-spinal fluid. Except on one occasion more cells were found in the fluid removed by lumbar than by suboccipital puncture. The globulin reactions were the same in both fluids. The pressure of the cerebro-spinal fluid was, as a rule, higher on suboccipital than on lumbar puncture. In the second case, which occurred in a man aged 22, suboccipital puncture was performed 11 times in the course of three weeks and anti-meningococcus serum, the exact amount of which is not stated, was injected. Lumbar puncture in this case was very difficult owing to the narrow space between the vertebræ, and only a few c.cm. of turbid fluid could be obtained by aspiration, whereas 20–30 c.cm. were readily withdrawn by suboccipital puncture. Comparative examinations of the fluids obtained by suboccipital and lumbar punctures were made with similar results to those in the first case. Recovery took place in six weeks. No bad effects from suboccipital puncture, nor failures such as "dry taps," or mixture of blood with the cerebro-spinal fluid, were observed in either case. Dr. Hartwich claims that suboccipital puncture causes less discomfort to the patient and is more easily carried out than lumbar puncture. It is of special value in cases in which lumbar puncture yields no result owing to the formation of fibrin clots during the acute stage or of adhesions during the stage of recovery. He also points out that owing to the necessity for repeated punctures, both in meningococcic and tuberculous meningitis, it is important to have more than one site for puncture at one's disposal. Moreover, in otogenic or other local variety of meningitis suboccipital puncture may prevent further spread of infection.

PHOSPHORESCENCE OF FISH AND MEAT.

A Service correspondent writes that he was consulted recently about a smoked haddock brought to him because it was luminous in the dark. Was it fit to eat? Although the streak of luminosity was quite definite there was no unpleasant smell, and as there was nothing else immediately available for breakfast, our correspondent passed it as sound. When cooked the luminosity had completely disappeared and the food gave rise to no unpleasant symptoms. The phenomenon of light production in dead tissues is very interesting; it appears to be due almost exclusively to the presence of photogenic bacteria, a fact which was recognised by Pflüger as long ago as 1875. The first isolation of one of these forms in pure culture was made by Fischer, who described its properties in 1887. Since then there has been a large amount of rather spasmodic and unconnected work expended on these curious species and a good many facts concerning them have become known. In nature they are generally found upon marine products, although also seen occasionally upon butchers' meat. They are also found invading crustacea and small marine metazoa in which they cause the phenomenon of phosphorescence and, not improbably, lead a symbiotic existence; they also appear to be the cause of the phosphorescence sometimes seen at sea. Photo-bacteria are widely distributed over the world's surface and have been found in India, Europe, and Australia. On at least two occasions human subjects have been described as giving off luminous sweat, and it is probable that there has been an invasion of the crypts of the sebaceous and sweat glands by photogenic organisms, pursuing a saprophytic existence on the surface of the body. Phosphorescence of consumable articles does not indicate unfitness for human food. Most of the known species flourish at low temperatures and can live and produce their specific effect at the temperatures employed for the storage of fish and meat at which ordinary putrefactive bacteria are not active. It is stated, indeed, that these organisms perish when active decomposition takes place in the material upon which they are living. They are readily culturable upon ordinary media, and experimental inoculation of animals has proved them to be non-pathogenic. In his monograph[1] on the Nature of Animal Light, Prof. E. N. Harvey, of Princeton, mentions some ways in which luminous bacteria have been made of service to man. Beijerinck has used them for testing the permeability of bacterial filters; Dubois and Molisch have suggested them as an illuminant in powder magazines where any sort of flame would be dangerous. It is certainly possible in emergency to read the time in the dark by the light of a glow-worm, but so far, at any rate, low temperature illumination by living things has not been exploited to any great extent.

THE LIMITATION OF HARMFUL DRUGS.

In view of the forthcoming Second International Conference on Opium, which has been summoned in Geneva for Nov. 17th to consider the best means of suppressing the abuse of morphine, cocaine, and other dangerous drugs, there is a special interest in a recent report of the International Institute of Agriculture in Rome on the question of the substitution of other crops for the opium poppy and the coca leaf. This report is the result of an investigation undertaken by the institute at the request of the League of Nations, and deals with an important side of the problem. It will be the work of the November conference to draw up a convention limiting the world's production and manufacture of harmful drugs to the world's medical and scientific needs. Undoubtedly the most difficult problem facing the conference is that of the limitation of production, since the largest of the great opium-producing countries—namely, China—has very little control over its own people, and the opium poppy is so valuable a crop. It has been found that the coca plant, from which cocaine is derived, could be replaced by the cinchona tree, the tea plant, the coffee tree, and the rubber tree; but whereas an area planted with coca will yield £146, the same area planted with cinchona produces £134, with tea £98, with coffee £80, and with rubber only £49. Furthermore, land suitable for coca cultivation is not always entirely suitable for cinchona cultivation. As regards the opium poppy, statistics are less reliable, owing to the varying contents of morphine in the opium grown in different countries. It is also a very valuable crop, and none of the plants which have so far been suggested for substitution would be as profitable. The best substitutes involving the least financial loss are plants producing valuable essential oils such as the citronella, geranium, rosa, and perilla (lemon grass). In the meantime, the League's Advisory Opium Committee has succeeded in drawing up certain concrete proposals, which are to serve as a basis for the discussions of the November conference, and which have now been circulated to all the States taking part in it, including non-members of the League. Amongst other suggestions, it is proposed that each country becoming a party to the convention should furnish every year an estimate of the raw material and manufactured drugs which it would require during the year and undertake further not to import more than was specified in its yearly estimates. These estimates, together with other statistics, would be sent to a central board, which would thus be in a position to follow the course of the international traffic, and see to it that the exports or imports into any country did not exceed the original estimates furnished by that country. A number of important provisions designed to strengthen the existing Hague Convention of 1912 will also be considered by the conference. The system of import and export Government licences instituted by the League, and already enforced by many Governments, whereby an export licence is only issued by the Government of the exporting country on the production of a certificate from the Government of the importing country, will be further extended. Provisions are also proposed to ensure that drugs which are brought into free ports do not escape control, and special arrangements are suggested for safeguarding the "entrepôt" trade as carried on by means of bonded warehouses. Other proposals are that the coca leaf shall be brought within the Hague Convention and that the definition of cocaine shall also include the artificial product obtained by chemical synthesis.

Finally, the Advisory Committee has appended two recommendations for the consideration of Governments. The first of these is based on a provision in British law, which has been found extremely useful in dealing with illicit traffickers, who, while residing in one country, organise or arrange for illicit transactions in another country. The second is intended to meet a very serious difficulty, which is caused at present by the lack of any control over the exports from certain producing countries. Large consignments of raw opium without any restriction are being exported to the Far East under false declarations of destination for the purposes of the illicit traffic, and are being smuggled into China and elsewhere. It is accordingly proposed that Governments should exercise a control over the conveyance of opium and other materials or drugs in ships sailing under their flag.

THE NEW GOVERNOR OF MAURITIUS.

THE appointment of Sir Herbert Read, one of the Under Secretaries of State for the Colonies, to be Governor of Mauritius and his consequent departure from the Colonial Office are events of very considerable importance in the realms of tropical medicine and hygiene. Those medical men who have been privileged to work with him at the Colonial Office will view the change with mixed feelings. They will be glad to know that the important work of retrieving the sanitary condition of Mauritius, inaugurated by the retiring Governor, Sir Hesketh Bell, is assured of sympathetic and skilled consideration under the ægis of his successor, and they will regret parting with Sir Herbert Read, who, for so many years, has been the official at the Colonial Office most intimately concerned with questions of medical and hygienic importance in our overseas possessions. Sir Herbert Read is not one of those who desire to be for ever in the limelight. He works quietly but none the less effectively, and his medical and veterinary colleagues upon many committees can testify to his zeal and unfailing courtesy. For a layman his record has been remarkable and his activities on the medical side of official life are, in part at least, to be attributed to the fact that he was private secretary to Mr. Joseph Chamberlain at the time when that statesman, prompted by Sir Patrick Manson, evinced a keen interest in the health of our tropical possessions, more especially in those on the once dreaded West Coast of Africa. Mr. Read, as he then was, filled the post of chairman of the Committee appointed in 1901 to report on a scheme for the amalgamation of the medical services in the West African colonies and protectorates. Since then he has been closely associated with all questions relating to tropical medicine and hygiene in British tropical Africa and also in other parts of the Empire, and he has been largely instrumental in the establishment of the Tropical Diseases Bureau, which developed from the Sleeping Sickness Bureau, and of the Imperial Bureau of Entomology. Deeply interested in African sleeping sickness and its relation to big game, he was concerned in obtaining the appointment of an Interdepartmental Committee which in 1913–14 considered these subjects and issued a report regarding them. He had previously been a member of the International Conference summoned to inquire into that disease, and it was as a result of this Conference that he took the steps which led both directly and indirectly to the establishment of the above bureaux. He has also represented the Colonial Office in the various negotiations as regards tropical research with which the Royal Society has from time to time been associated. Perhaps his most important service to the cause he has so much at heart has been rendered as chairman of the Colonial Advisory Medical and Sanitary Committee. He has presided over the meetings of this body since its inception, and his tact and kind consideration, coupled with his ability for getting business put through, have greatly aided the deliberations. As chairman of the Tropical Diseases Research Fund he has also been able to help on the good work, and his activities in all these various directions were suitably recognised when the Royal Society of Tropical Medicine and Hygiene elected him one of its honorary Fellows. All those who have been privileged to come into close contact with Sir Herbert Read in connexion with medical and sanitary work in the tropics will unite in wishing him every success in his new sphere of duty, where he will have opportunities of applying practically those principles with which long years of devoted service at the Colonial Office have rendered him familiar.

THE ROYAL SOCIETY'S EXHIBIT AT WEMBLEY.

THE great exhibition at Wembley closes at the end of the present month, and the opportunity should not be lost by those who have not done so already of seeing the exhibit of pure science arranged by the Royal Society in the British Government Pavilion. The heart-lung apparatus shown by Prof. E. H. Starling has been employed by him and by his pupils for many important researches. It enables the mammalian heart to be studied under exactly controlled conditions. The demonstration of physical apparatus by Prof. A. V. Hill includes recording thermometers, string galvanometer, the hot-wire sphygmograph, and the "Katharometer" for determination of CO_2. There are also shown the apparatus used for experiments on the energy expended in movement by Prof. E. P. Cathcart, a demonstration of the physiological action of light by Dr. D. T. Harris, and one by Dr. H. Hartridge and Mr. F. J. W. Roughton on apparatus for the study of blood gases. These are all of real interest to those who have enjoyed an exact scientific training, although it may be doubted how far this exhibit can be expected to appeal to the general public. It has, however, the admirable lucidity of a lecture by one who has such mastery of a difficult subject that he can deal with it in simple terms. The "Handbook" (obtainable from Messrs. A. and F. Denny, Ltd., 163a, Strand, London, W.C. 2, 1*s.* 3*d.* post free) contains, besides a description of the exhibit, articles on the Origin of Man, by Dr. A. Smith Woodward; on the Circulation of the Blood, by Prof. Starling; on the Biological Action of Light, by Dr. Harris, and on Muscular Work, by Profs. Hill and Cathcart. These summaries by experts are of especial interest. The Royal Society evidently regards medicine as a branch of biology, for in Exhibit 223 we find among the portraits of eminent biologists those of William Harvey and Joseph Lister. This is taking a broad view of the situation.

STARCH IN DIABETIC FOODS.

THE chief complaint of a patient with diabetes mellitus concerns the reduction of the amount of starchy food and especially of the bread which is ordered. It is natural, therefore, that many attempts should have been made to prepare a substitute which will meet the approval of the patient. Bread contains starch, protein, and fat, and it is possible to remove nearly all the starch, leaving only the protein and fat. The more complete the removal of the starch the more difficult it is to produce a food which is at all palatable. But as the result of prolonged efforts a series of foods have been made which contain practically no starch, and although no one would eat them of choice, yet they are by no means unpalatable. However free from starch these foods are, the patient should remember that the caloric value of 1 oz. of a diabetic food is greater than that of 1 oz. of ordinary bread. This is partly due to the increase in the proportion of fat which has a higher caloric value than starch, and partly to the smaller proportion of water which the foods usually contain. Since the total caloric value of the diet must be considerably reduced the patient often has to make his choice between a diabetic food and other foods such as meat, fish, eggs, and cheese. Under these circumstances the wise patient usually takes a minimal amount of the diabetic food. Although the purest diabetic foods contain very little starch, there are others which contain a considerable amount. It is unfortunately a common occurrence for a patient who has made a fair recovery of sugar tolerance to return after a few weeks absence, either passing sugar or with a considerable elevation of the blood-sugar. On inquiry the statement is often made that a diabetic food has been recommended by friends and bought from a small baker. Testing the bread with a weak solution of iodine is sufficient to show at once that the sample contains much starch. It is not always the small baker's bread which has been the cause of the return of symptoms. Patients are only too apt to eat anything which is called a diabetic food without reading the literature which is supplied with the food. One well-known company, for instance, supplies a diabetic bread which contains 40 per cent. of starch as compared with 55 per cent. in ordinary bread, and the fact that one-third of the starch has been removed is clearly stated in the advertisement. In spite of the removal of this amount of starch the bread still remains fairly palatable, and the patient who eats one and a half ounces of it should realise that he is taking the same amount of sugar as if he were eating one ounce of ordinary bread, while the caloric value is greater. The introduction of insulin has been responsible for the much greater attention which is being paid to the details of diet, and patients are taught to think of their food in terms of caloric value, sugar, protein, and fat values. It would therefore be a great help if the makers of the various foods would state clearly on the label as well as in the literature supplied the following data. One ounce of —— contains *a* g. of starch, *b* g. of protein, *c* g. of fat, and *d* total calories. If this were done it would assist the luckless patient who already has sufficient troubles to contend with.

A NEW METHOD OF SPHYGMOGRAPHY.

IN a volume[1] which maintains the high typographical standard of modern Spanish medical works, Dr. D. Miguel Gil-Casares of Santiago describes a new and ingenious method for obtaining sphygmographic records and the instrument he uses for the purpose. He calls his instrument a "palograph" and the method "palography," coining the words by derivation from the Greek *πάλλω, παλλομαι*, to oscillate or palpitate. The arterial, venous, or cardiac impulse is transmitted not, as in the ordinary sphygmograph, to a movable arm whose extremity records its movements on a surface of lamp-blacked paper, but to a column of some highly mobile fluid, such as ether or acetone, in a U-shaped tube, the movements of the liquid surface in the open limb of the U-tube being recorded photographically on a moving sheet of sensitised paper by the passage through it of a beam of light. The author states that Volhard's experiment for demonstrating the asynchronism of the carotid and jugular pulses by connecting manometrically to each a U-shaped tube containing a column of liquid, the liquid being coloured differently in the two tubes, gave him the idea that it might be possible to obtain a photographic record of the oscillations of the liquid due to the venous or arterial impulse. In the course of experiments on the subject the author noticed that a beam of light directed through a limb of the U-tube with its column of liquid on to a sheet of paper, gave, after passage through the liquid, a central bright line bordered by two dark bands. A profile of the tube with uniform illumination was observed where the beam had traversed the part of the tube containing air, while, at the level of the meniscus, a dark spot, or rather a small dark triangle with apex downwards, separated the two former areas. If for the sheet of ordinary paper a moving sheet of sensitised paper was substituted, the effect produced was that of a triple band with a dark lower portion where the beam had passed through the column of liquid, an upper, less dark, portion where it had passed through the air above the liquid, and a bright line, separating the other two, where the concave meniscus, acting as a double prism, had cut off the light from that portion of the sensitised paper immediately behind it. If now an arterial, venous, or cardiac impulse be transmitted to the liquid in the tube the triple band is thrown into waves. Its parts, however, retain their relative positions and the result is the production of a beautifully clear and bold photographic representation of the impulse under investigation. The author discusses the application of his method to the investigation of various pathological states, and his book is illustrated by numerous interesting, and indeed beautiful, "arteriograms," "phlebograms," and "cardiograms." His description of the instrument he has designed for the production of these photographic tracings (made by the Berlin firm "Sanitas") is not very clear. The actual instrument may, however, explain itself.

WELFARE WORK IN INDUSTRY.

THE report which we print elsewhere (p. 718) of the annual conference of the Institute of Industrial Welfare Workers gives good reason for the belief that if we are to have healthy and contented workers there must be close coöperation between the doctor and the psychologist on the one hand and the welfare worker on the other. For the welfare worker has come to stay. The number of women employed in this capacity has risen from a pre-war total of 25 to over 600. If the valuable work which is being carried out by the Industrial Fatigue Research Board and the Institute of Industrial Psychology, for example, is to be successfully applied to industry the welfare worker must help to prepare the way, for the workers are naturally suspicious of psychology, as one of their spokesmen said at the conference mentioned above. At the same time, the effect of the scientific study of industry is to make fatigue less prevalent, to make work "easier" in the sense that unproductive and misapplied energy is curtailed, and the workers themselves will be the first to benefit, quite apart from the economic aspect of increased output. In the heat of discussion, one of the employers present made the strange indictment of the medical profession when he said that some doctors only went near a factory in order to collect their fees, that they never saw the workers at work, and that they frequently never saw the workers they were supposed to examine. The general feeling of the conference was that such an experience is fortunately rare, but Dr. W. F. Dearden in the course of his paper urged to good purpose that the physical fitness of workers could only be fairly assessed in the light of the work they had to do, and he encouraged all doctors in industrial districts to familiarise themselves with the work their patients engage in. Another point of view was that expressed by Dr. A. G. Yates, who took the chair at one of the meetings, when he suggested that welfare workers could pass on to the workers much information about health in general; they might, for instance, preach the value of sunlight and the importance of proper diet in the light of recent research. The welfare worker would thus become the link between the factory doctor or psychologist and the workers. The health of the industrial population is a great national problem, and especially in the present period of depression the waste caused by ill-health and unproductive work should receive consideration.

THE first meeting of the Royal Commission on Lunacy and Mental Disorder will be held at the Royal Commission House, 5, Old Palace Yard, Westminster, on Tuesday, Oct. 7th, at 10.30 A.M., when evidence will be given by the Board of Control. On the following day at the same time the Ministry of Health and the Lord Chancellor's Department will give evidence.

THE Guild of St. Luke will hold its diamond jubilee service at St. Paul's Cathedral on Tuesday, Oct. 21st, at 7 P.M., when the Bishop of Truro will preach. Academic dress will be worn. Tickets may be obtained on sending stamped addressed envelope to Rev. H. Kirkland-Whittaker, M.D., Chaplain's House, Banstead Downs, Sutton, Surrey, or to Dr. Dorothea Brooks, 65, Park-road, Battersea, London, S.W. 11.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XC.—COMMON FRACTURES OF THE ELBOW-JOINT IN CHILDREN.

IT is generally recognised that all fractures about the elbow, excepting fracture of the olecranon, should be treated with the elbow fully flexed and forearm supinated. In practice it is important to realise that good results will not be obtained unless the displacement of the fragments is first reduced. Swelling of the limb may tempt one to leave the elbow at a right angle, with the result often that further flexion cannot be obtained when the swelling has subsided. Hence it is important to judge the appropriate methods of treatment for each fracture so that good function is produced and complications are avoided.

Supracondylar Fracture.

Supracondylar fracture (separated epiphysis of the lower end of the humerus) is a common accident in children, occurring usually between the ages of 5 and 10; it may occur before the age of 5 and in older children up to 15 or thereabouts. The injury is frequently called a separated epiphysis, but the line of fracture is on the diaphyseal (shaft) side of the epiphyseal line, so that the lower fragment consists of the epiphysis and some of the soft bone of the shaft adjacent to it. This fragment is displaced upwards and backwards, but, in addition, often laterally, either inwards or outwards. The radius and ulna move with the lower fragment. When the child is seen shortly after the accident the diagnosis causes little difficulty, but when swelling has commenced the bony points cannot be felt. X ray examination is essential: (*a*) to confirm the diagnosis, (*b*) for comparison with another plate taken after correction, and (*c*) for medico-legal reasons. Both lateral and antero-posterior views are required.

(1) *Reduction.*—In order to get efficient reduction, which is essential for a good functional result, the child must be given a general anæsthetic. The limb is then washed, dried, and powdered. An assistant, who may be a nurse, holds the arm firmly some inches above the elbow, and applies counter-traction at the appropriate time. The surgeon grasps the forearm in his right hand and holds it fully supinated. He places his left hand round the elbow, so that the thumb is against the front of the lower end of the shaft of the humerus and the fingers at the back of the joint over the lower fragment and olecranon. Traction is then applied to the forearm in the axis of the limb, allowing for the carrying angle at the elbow. This must be very strong and maintained during the subsequent manipulations. The elbow is then hyper-extended to free the lower fragment; next it is gradually flexed, during which manœuvre the left hand presses the humeral shaft backwards and the lower fragment and olecranon forwards. This will not be possible unless the strong traction is continued. After satisfactory reduction the operator carries the elbow into full flexion with the forearm fully supinated. It is judicious for a radiogram to be taken to determine if reduction is complete.

(2) *Fixation.*—Powder is dusted into the fold of the elbow and a small piece of dry boric lint pushed into it. The wrist has then to be fixed to the upper part of the arm. A piece of felt or cotton-wool about three inches wide is wrapped round the lower end of the forearm above the wrist and round the upper part of the arm. A piece of adhesive strapping two inches wide is carried round the arm and forearm over the felt. The radial pulse and finger-nails should then be examined to make certain that no interference has been made with the circulation. If the child is under 6 the flexed arm is then kept across the chest by two turns of a six-inch flannel bandage round the body and arm. An older child should have the wrist slung in front of the chest by a "collar and cuff halter." This consists of a bandage or webbing round the neck fixed to the wristlet of the bandage. It is more comfortable if the bandage round the neck is passed through a piece of rubber tubing, and the forearm can only be kept fully supinated if the connexion between the collar and cuff is made on the inner side of the wrist. The elbow itself is left uncovered.

FIG. 1.

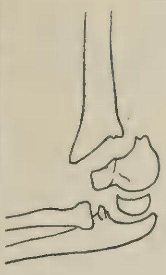

Diagram of supra-condylar fracture.

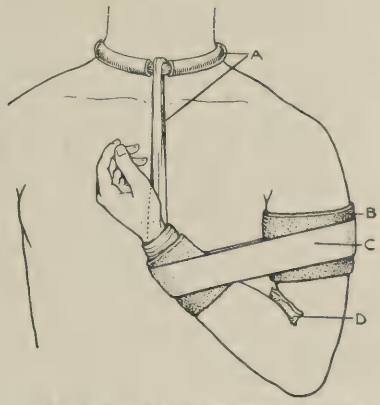
FIG. 2.



Method of fixation of arm. A, Collar and cuff halter. B, Felt. C, Adhesive strapping. D, Boric lint.

(3) *After-care.*—The limb is kept in this position for two weeks, during which period no movements should be allowed at the elbow, but finger and thumb movements should be encouraged from the commencement. Active or passive movements are dangerous and predispose to complications. Massage may be harmful if rough kneading is employed; it should be very gentle and applied where the elbow is swollen. At the end of two weeks the strapping is cut off, the child told to touch the shoulder with the fingers, and the forearm then let down a little every two days. It can be fixed with a flannel bandage round the arm and forearm in place of the strapping, or by the halter. Each time it is let down the child should be made to touch the shoulder, to show he has retained the full flexion. If he cannot do this, full flexion should be maintained for a few days longer. As a rule, in children the elbow can be at a right angle in three weeks after reduction. Shortly after this fixation can be discarded, but it may be wise for the child to wear a sling when out of doors. At this time he should be encouraged in active movements to regain the extension, such as pulling on a chair, but passive movements should be avoided as much as possible. If the elbow is greatly swollen, as will usually be the case if the patient is seen a day or two after the injury, treatment will have to be somewhat modified. Reduction should be carried out and the limb powdered, but full flexion cannot be obtained. Adhesive strapping should be avoided, as it may cut into the skin. Hence the forearm and arm should be bound together by two turns of a flannel bandage, in a position of as much flexion as can be obtained without causing undue pressure in front of the elbow. The wrist is then fixed in front of the chest by a collar and cuff halter. As the swelling subsides this can be drawn up every two days so as to increase the flexion and the bandage made more tight round the arm and forearm. The remainder of the treatment is as described above.

Difficulties and Complications.

(1) *Failure of Reduction.* Should reduction not be obtained, the best results follow open operation for reduction of the lower fragment.

(2) *Great Swelling* and blistering of the skin. The latter may be associated with the former. The region of the elbow should be painted with iodine and blisters pricked with a sterile needle and a dressing

applied. The modification of the treatment necessary in this condition has already been described.

(3) *Ischæmic Contracture* (Volkmann's paralysis). This condition is probably preventable by the avoidance of tight bandages round the elbow and by care in regulating the flexion, so that it is not so great as to cause compression of the brachial artery.

(4) *Myositis Ossificans* may follow this fracture if the reduction is performed roughly and if massage and movements are carried out injudiciously. It occurs more readily if the elbow is kept at a right angle. Its presence can be diagnosed sometimes as early as three weeks after the injury and straightway appropriate measures should be adopted to aid its disappearance. Absolute fixation of the elbow in as much flexion as is comfortable is indicated for some months. Massage and all movements are to be avoided, and operative treatment for removal of the bony mass should not be undertaken until after an interval of at least six months. The results of early operative treatment for this condition are disastrous, and late operation often fails to cure the condition owing to the tendency for the new bone to re-form.

(5) *Nerve Injuries.* Either the musculo-spiral, ulnar, or rarely median nerve may be paralysed as a complication of this fracture. In the case of the former a small "cock-up" splint should be worn to prevent the wrist dropping as soon as the arm is put in a sling, and electrical treatment commenced for the paralysed muscles. If there is no sign of recovery in three months, operative interference becomes necessary. When ulnar paralysis is associated operation is indicated for reduction of the fracture and inspection of the nerve.

(6) *Deformity* may occur at the elbow after partial or incomplete reduction, or if the forearm is brought into wrong alignment with the arm. Late operation may be required for cubitus valgus or varus.

Other Fractures.

Fracture of the external condyle in children consists of a separation of the capitellum and a small portion of the outer part of the lower end of the humerus from the humeral shaft. It is not very uncommon. The exact nature of the injury must be diagnosed by a skiagram to determine if there is serious displacement or not. If there is no displacement the elbow is fully flexed and the forearm supinated, as described above. Should displacement be present, reduction can be attempted under anæsthesia, but open operation may be required.

Fracture of the internal condyle is unusual before 10; in children similar treatment to that of fracture of the external condyle is applicable.

The *T- and Y-shaped fractures*, when there is a more or less transverse fracture of the lower end of the humerus with a line of fracture also into the elbow-joint, are uncommon in children. Treatment consists of open operation if there is gross displacement, but if the fragments are in good apposition the elbow should be kept fully flexed and the case treated similarly to the supracondylar fracture.

The *coracoid process of the ulna* is very rarely fractured in children in association with a backward dislocation. Injury to the *upper radial epiphysis* (the head) is also rare in children. The elbow should be kept flexed in each case. In the former case the dislocation is reduced first.

Summary.

In the treatment of fractures about the elbow-joint in children the following points are of importance: (1) efficient reduction; (2) position of acute flexion with supination; (3) avoidance of unskilled massage and early movements; (4) avoidance of lateral or side splints, which tend to deformity at the elbow, and right-angled anterior or posterior trough splints, which do not keep the fracture reduced and cause other untoward results; (5) operation is indicated when reduction is impossible or deformed union is present.

THE BLOOD PLATELETS AND THEIR PLACE IN MEDICINE.

By S. C. Dyke, M.D. Oxf., M.R.C.P. Lond.,
CONSULTING PATHOLOGIST TO THE WOLVERHAMPTON
AND STAFFORDSHIRE HOSPITAL.

The history of the blood platelets or thrombocytes in the past has been a chequered one; first studied with care and accuracy by Bizzozero in 1882, their existence has since been repeatedly affirmed and denied, and innumerable sources of origin and functions assigned to them. Bizzozero himself believed them to arise in the bone marrow from a genetic line distinct from that of the other formed elements of the blood; others have regarded them as a precipitate formed in the plasma at the moment of shedding and as having no existence in the circulating blood; Hayem thought that they were young red cells, and accordingly named them "hæmatoblasts," a title which still encumbers hæmatological nomenclature more particularly in France. It remained for an American worker, H. Wright,[1] to promulgate what appears to be the true theory as to their origin. This worker on the basis of certain tinctorial affinities between the platelets and the cytoplasm of the megakaryocytes on myeloplaxes of the bone marrow postulated a relationship between the two. He demonstrated the power of the megakaryocytes to throw pseudopodia into the sinuses of the bone marrow and produced strong evidence for the belief that these cytoplasmic processes becoming detached from the parent cell were carried in the blood as the platelets. All the weight of such evidence as has accumulated since Wright published his theory is in its favour. His views gained complete acceptance in America several years ago, and it is a demonstration of the value of a sound theory to practical medicine that his work soon found important applications at the hands of Duke and other American clinicians. In this country, possibly because they were based on purely morphological grounds, Wright's views did not gain general acceptance, and the very existence of the platelets continued to be doubted.

It remained for Ledingham[2] in 1914 to demonstrate beyond a doubt the existence of the platelets as entities by preparing, with guinea-pig platelets as antigen, an anti-serum, capable, on parenteral injection, of destroying the platelets of the same species. This work has since the war been assiduously followed up by Bedson, who has not only confirmed this observation, but has shown[3] that the disappearance of the platelets from the blood of the injected guinea-pig is followed by severe purpura. Furthermore, by preparing anti-sera against the other formed elements of the blood, Bedson has been able to show that none of these bear any close relationship to the platelets and certainly cannot serve as their sources of origin; anti-sera active against red cells, or against the granular or non-granular white cells are without effect upon the platelets.

The Effects of Thrombopenia.

That the elements are entities there can now be no reasonable doubt; the complete proof of their sources of origin awaits demonstration, but as to their relationship to the hæmorrhagic diathesis and to the production of purpura, the proof, both experimental and clinical, is now complete. It has been established that destruction of the platelets in the guinea-pig is followed by purpura; clinically Duke[4] has shown that in the human subject, when the platelet count descends below 60,000 per c.mm., there is an abnormal tendency to bleed, that when it falls below 10,000 hæmorrhage becomes severe and when below 1000 fulminant. He has, moreover, demonstrated that such a thrombopenia or diminution in the platelet count is associated with prolongation of the bleeding time and failure of the blood-clot to contract, though the actual clotting time remains normal.

Frank[5] and many other workers on the continent and in America have fully confirmed Duke's observations. Frank has endeavoured to evolve a hypothesis which should correlate all the forms of purpura associated with thrombopenia. He defines three main forms of this condition: intermittent thrombopenia, in which the platelets only occasionally fall to a low level and in which the purpuric attacks consequently occur at intervals; essential thrombopenia, in which the platelet count is chronically low and in which there is a tendency to hæmorrhage and bruising on slight trauma; and aleukia, in which both the granular leucocytes and the platelets are greatly reduced in numbers and the hæmorrhage is fulminating and usually fatal. All these forms Frank believed to be due to a primary deficiency of the bone marrow, the last only being found in conjunction with and as a result of a completely aplastic state of the hæmatopoietic system. Cases of this type in which infection has followed upon the myelophthisic condition have recently been described by the present writer[6] in THE LANCET.

The Rôle of the Spleen in Thrombopenia.

Enlargement of the spleen is a feature of most of the cases described above, such spleens on histological examination frequently showing masses of platelets in the sinuses; this has led some workers to believe that the actual cause of the thrombopenia might be the destruction of the platelets by the spleen. It has remained for Bedson, as recently pointed out in THE LANCET,* to demonstrate clearly by experiment the thrombocytolytic action of the spleen. He showed that in the guinea-pig splenectomy is followed by a great but temporary rise in the platelet count; so great is this rise that recently splenectomised guinea-pigs are capable of standing without symptoms a dose of anti-platelet serum which in unsplenectomised guinea-pigs produces violent purpura. Bedson, however, found that even in splenectomised animals the platelet count soon reverted to a normal level. This last observation makes it difficult to understand the permanent good results reported recently as obtained by splenectomy in human cases of purpura hæmorrhagica.

A possible explanation of this is offered by the recent work of Seeliger[7] in Germany. This author, by the examination of marrow obtained by sternal puncture from patients suffering from purpura, claims to have been able to divide his cases into two classes. In the first the bone marrow showed megakaryocytes in normal or excessive numbers, these, however, being characterised by the absence of the normal granulation of the cytoplasm. In the second class the marrow was aplastic, showing few hæmatopoietic cells of any sort. In the first class the spleen on histological examination was found to be packed with platelets; in the second platelets were absent from this organ. The cases of the first type Seeliger regards as dependent upon an abnormality of the megakaryocytes, which consequently produce abnormal platelets, and these being abnormal are removed by the spleen as soon as liberated in the circulation. To this type of case Seeliger would limit Frank's term "essential thrombopenia." The second class of case he regards as dependent upon a failure of function upon the part of the red marrow, the platelets, along with the granular leucocytes, undergoing a diminution as a result of the collapse of the machinery for their production; to this type he would limit the term "aleukia." Beneficial results are only obtained by splenectomy in the first class of case, such benefit being due to the withdrawal of the thrombocytolytic activity of the spleen and explicable on the assumption that even an abnormal platelet is better than none at all. In the second class of case the thrombopenia is dependent not upon the thrombocytolytic activity of the spleen, but upon actual failure of platelet production at its source, and in this type splenectomy is of no avail.

The Platelets and the Bone Marrow.

Leaving out of the question the thrombocytolytic action of the spleen, it is apparent that on theoretical grounds any condition of marked general activity of the bone marrow should be associated with an increase of the platelets. This has been put to the test of observation by Dr. G. J. Crawford, who reported the results of his work in a recent number of THE LANCET.[8] Dr. Crawford made counts of the platelets and of the granular and non-granular leucocytes in a number of conditions, some associated with an exaltation and some with a depression of the activity of the hæmatopoietic system. A study of his figures shows that, roughly speaking, the platelets are increased when the bone marrow is active and decreased when the contrary is the case. This is particularly well shown in the leukæmias; in the myeloid type a great excess of the leucocytes of the granular order is always associated with an intense thrombocytosis, the platelets in one case reaching nearly a million and a half per c.mm.; in the lymphatic type, on the other hand, the platelet counts are invariably low.

One of Dr. Crawford's cases also shows the marked effect of splenectomy in the human subject, the platelet count rising from under half a million before the operation to over a million shortly afterwards. The evidence marshalled in this paper points clearly to the bone marrow as the source of the platelets and further indicates their affinity, however remote, with the leucocytes of the granular order.

Interference with the function of the bone marrow as the source of the platelets offers a possible explanation of the thrombopenia observed by Cramer, Drew, and Mottram[9] as a result of keeping rats upon a diet deficient in vitamin A. In view, however, of the fact first demonstrated experimentally by Delrez and Govaerts[10] that the platelets tend to accumulate about any foreign particles in the blood-stream, bacteria included, it is possible to offer another explanation of this phenomenon. There is good reason to believe that upon diets deficient in either the A or C vitamin the gut wall becomes so damaged as to permit of the passage of micro-organisms into the blood-stream; such dissemination of organisms into the blood, if plentiful and long continued, might conceivably bring about a considerable thrombopenia. Observations upon the platelet counts in chronic microbic diseases might throw some light upon this point.

One of the few such observations is the article by Dr. R. G. Bannerman,[11] which recently appeared in THE LANCET, and this it is somewhat difficult to fit into the picture as we now see it. As the result of a long series of observations made upon patients suffering from pulmonary tuberculosis, this worker has arrived at the conclusion that a favourable prognosis is indicated by a low and the reverse by a high platelet count. In his series all those cases in which the platelet count remained below 400,000 per c.mm. tended to do well, while those in which it rose above 510,000 per c.mm. on the whole went steadily from bad to worse. It is difficult in the light of present knowledge to offer any explanation of this phenomenon, but if confirmed it should prove of the greatest value in the prognosis of pulmonary tuberculosis.

The recent appearance of two papers on the subject in THE LANCET with other recent work seems to indicate that, after a long period of neglect, the blood platelet is receiving its meed of attention from British clinicians; that this revival of interest should have followed so speedily upon the acquisition of the lately won knowledge of the nature and rôle of these bodies must be more than a coincidence, and serves to demonstrate the value of the experimental method to medicine.

THE HEALTH OF THE ARMY IN 1921.*

THE medical profession has been eagerly awaiting this report by Sir William Leishman, Director-General of the Army Medical Services, who has already taken his share in producing the Medical History of the War, nor will any disappointment be felt at this compilation on the health of the army in a time of official peace. The present report is numbered Vol. LVII.; its predecessor, Vol. LVI., covered the first seven months only of 1914, as the reports during the war years were included in the Medical History of the War, while for the year 1920, owing to the abnormal conditions which then existed, it was decided that no report should be published. The report for 1921 is of great importance, as it tells of the careful organisations built up in the army for the study of hygiene, of pathology, and for the care of the soldiers' teeth. Sir William Leishman explains the delay in submitting the report as due to the many changes in the composition and distribution of the army which took place both during and after the period under review in connexion with the gradual reversion of the army to a normal peace footing.

The main body of the report is divided into five sections, dealing with (1) general considerations, (2) medical examination of recruits, (3) hygiene, (4) pathology, and (5) dental treatment.

General Considerations.

The health of the army in 1921 had considerably improved since the preceding year, but continued to be less satisfactory than before the war, owing to the poor physical condition of many of the recruits hastily enlisted to fill the vacancies of those demobilised on the conclusion of war. This, coupled with the fact that medical officers with experience in the medical examination of recruits were not always available to carry on this important work, led to a large number of men being passed as fit for service in the army who would otherwise have been rejected. But a return to the high standard which existed in 1913 may be expected at no distant date.

The average strength of *officers* in the regular army in 1921 was 13,897, of which the rate of admission to hospital per 1000 was 374·2, and the death-rate 5·9. The chief causes of illness were (expressed as the ratio per 1000) diseases of the digestive system (other than inflammation of the tonsils and of the liver) 56·6; local injuries, 52·8. Gunshot wounds accounted for eight deaths in Ireland, but no "wounds in action" are returned. The number of officers "finally discharged" is not mentioned.

The average strength of *warrant officers, non-commissioned officers, and men* was 239,525. The ratio per 1000 of illness was 650, with 4·2 deaths and 27·48 final discharges. The most frequent admissions to hospital were due to malaria, diseases of the digestive system, and local injuries, while the most frequent causes of death per 1000 were: injuries 1·34, pneumonia 0·52, malaria and diseases of the digestive system, each, 0·27 per 1000. The case-mortality of enteric was 8·33; of pneumonia 11·7; of small-pox 22; and of the four cases reported of meningococcus infection, three died. Suicides, it may be said here, are not counted into the total of deaths. Troops on board ship numbered 4551, and had relatively few admissions to hospital (414·6 per 1000) and only three deaths, two from pneumonia, yet there was a relatively higher case incidence of influenza, pneumonia, and bronchitis.

For this year for the first time a table is given summarising the health statistics of soldiers' wives. Their chief reason for admission into hospital was diseases of the generative system, in a ratio of 50·3 per 1000; diseases of the digestive system came next, 33·3. The incidence of pneumonia and bronchitis among the women is only a quarter of that among the men. There were on the Married Quarters Roll this year 24,684 children, with a death-rate of 12 per 1000, due chiefly to diseases of the digestive system and to malaria. Mention is made of 2709 cases of parturition.

Medical Examination of Recruits.

The statistics are, it is observed, compiled from the "recruiting year" (Oct. 1st, 1920, to Sept. 30th, 1921), in which 53,142 recruits were taken into the army and 32,962 candidates were rejected, either at once or within six months. The rejections were more numerous in 1921 than in 1913 (354·01 per 1000 as against 202·5). This was partly due to the standards having been raised, particularly as regards teeth and eyesight, and partly because men could now be rejected within six months of enlistment, not only in their first three months, as was the rule before the war. Also there was not, in 1921, time to "nurse" into efficiency the less physically fit recruits. Of candidates examined and passed, 791 per 1000 were natives of England, 110 of Scotland, 95 of Ireland, and 4 were born in British Colonies and foreign countries. The chief causes of rejection on examination were: sub-standard chest measurements 33 per 1000 of total candidates; defective vision, 58; heart diseases, 38; teeth lost or decayed, 35; flat-feet, 27. Of those at first received but rejected later the chief disabilities were middle-ear disease and defective vision. Tubercle claimed a rejection ratio of 4·3 per 1000 on first examination and 0·28 later; in 1914 the figures were 2 on first examination, and 0·14 later.

Hygiene.

The great difference between the present report and those that preceded it lies in the changed outlook. Former reports told of events passed, here aims for the future are suggested. The hygiene of the army is being systematically assured. Commanding officers are responsible for the sanitary condition of the areas of their units, so they and their staffs must be educated. Consequently, courses of instruction for combatant officers and personnel are held at the Army School of Hygiene. Six lectures on hygiene are given each term to senior cadets at Woolwich and Sandhurst. Instruction is also given to all ranks at all stations. Junior officers of the R.A.M. Corps receive instruction at the College, and go through a practical course at the School of Hygiene. They take a senior officer's course at the College some eight years later. Officers and other ranks of the Corps who propose to specialise attend an advanced course at the College and Army School. There are deputy assistant directors of hygiene at important stations, assistant directors of hygiene are on the staffs of deputy directors of medical services of commands, and there is a director of hygiene on the staff of the director-general. Above all these is the Army Hygiene Advisory Committee, which has been in existence since 1919, on which sit representatives of the quartermaster-general's department and (since 1921) of the general staff. The objects of this new organisation are stated to be: (1) To bring under one directorate the hygiene specialist officers of the army. (2) To raise the standard of hygiene in the army, and to help it by fostering research. (3) To ensure that the welfare and health of the troops are carefully watched by officers who have made a special study of the subject, and thus not only improve the fighting efficiency of the army but effect a saving to the State by preventing wastage

from disease and physical inefficiency. Three reports of investigations under object (2) are mentioned in the report, but references to the places of publication would have been an advantage. In 1921, after considerable research, a new scale of rations was adopted, which might with advantage have been included in the report for the information of people who, in 20 or 40 years' time, may be examining these reports to decide what were the influences in 1921 bearing on some recently differentiated disease. Transports for troops have been considered, and space per man has been increased by 70 per cent. Barracks are being rebuilt and remodelled as funds become available; gas is being replaced by electric light in barrack-rooms; six linear feet of wall-space per man is required, as the necessity for this was brought forcibly to light during the influenza epidemic of 1918. Baths (shower, foot, and slipper) are being provided (probably with hot water, but this is not stated); cookhouses and dining halls are being improved, so that the serving of food shall be bettered, and that men may thus be induced to stay in barracks. More and better married quarters, better schools, and further improvements to hospitals will be provided as funds come in sight. Mother and child welfare schemes were undertaken at many stations; they were much appreciated, and admirably carried out. The disease that caused the greatest loss of service was *malaria*, with a ratio of cases of 99·8 per 1000 men, a death-rate of 0·27, and the rate of invalids discharged finally being 0·48. At Jenin, in Palestine, the number of cases was reduced by sanitary effort from 600 in 1920 to 2 in 1921. At Richon, in Palestine, *Anopheles maculipennis* was found to travel one and a half miles, for they disappeared when the suspected swamp one and a half miles away was drained. An increase of malaria in South China is ascribed to a long spell of dry weather. The Waziristan Force, with 1018·3 admissions to hospital per 1000 and a death-rate of 2·39, seems to have been the part of the army most severely attacked. *Venereal diseases* showed a maximum incidence in Constantinople (228·5 per 1000) and in Germany (169·2). The Eastern Command had the lowest rate with 36·0 admissions. The figures for the United Kingdom were 40·3 as compared with 74·0 for the whole army. The high prevalence in Constantinople is ascribed in this report (as in that of the Navy for the same year) to the multitude of unfortunate destitute refugees. Efforts are being made to reduce occasions of venereal infection by giving men greater comfort in their barracks, by sports and games, by education, by disciplinary insistence on notification and early treatment. Penalties imposed on men who contracted venereal disease did not win approval, and tended to concealment of the disease.

Disorders of the digestive system are a source of much distress to the young soldier, and are ascribed to his consuming too many sweet cakes and tea between meals. It is hoped to remedy this by better cooking and serving of meals, and by better dental treatment. We notice, however, that officers suffer from these diseases just as much as the men. Local injuries in riding schools, gymnasia, and on the football field cause great loss of service, and are being carefully watched with a view to prevention. *Boils*, which during the war were reported to be associated with deficiency of vitamin C, are specially prevalent in mounted corps, particularly if the barrack-rooms are over stables. *Sand-fly fever* gives rise to disability, but causes no deaths. The small-meshed curtain required to keep out the flies becomes intolerable in the hot airless weather when the insects are most numerous, and men will not sleep under them. The fever is most prevalent in Iraq, North (but not South) India, and in Egypt. *Influenza* was found to be best restrained by a preventive vaccine with streptococci, pneumococci, and Pfeiffer's bacillus. *Scabies* caused much loss of service, each of the 4900 cases averaging 11 days off duty. It was most prevalent in Germany, least in Iraq, and heavy at home, where there are more furloughs, with which its prevalence is officially connected. The Danish treatment of scabies,[1] which has shortened term in hospital by a half or even more, has now been adopted by the army.[2] One case of *actinomycosis* is mentioned in Ireland, and three of *encephalitis lethargica*. *Heat-stroke* came on at Basrah when the maximum shade temperature was 127° F.; 15 per cent. of the cases admitted alcoholic excess, and these all died; 18 per cent. were total abstainers and recovered.

Pathology.

An organisation similar to that described under hygiene, but wholly within the R.A.M.C., has been built up to study the pathology of the army; this trains workers at the College for the immediate identification of pathological conditions in order that early and accurate diagnosis shall allow effective measures to be instituted to curtail the spread of disease. Vaccines were made for the army at the College in 1921, and so, it is calculated, a sum of £20,000 was saved to the country by the R.A.M.C. An organised research was instituted on "catarrh," and *B. coryzæ segmentosus* was thereby brought specially to notice and added to the "anti-cold" vaccine, which thus had its efficiency, it is believed, increased. *Kala-azar* was found in two children in Malta, where many native dogs are infected with leishmaniasis. In the Rhine army it was thought that a small outbreak of *diphtheria* among bandsmen was spread by their instruments. *Vincent's angina* also occurred in that force, and 1125 cases out of the total force of 9870 were notified. American military surgeons, too, have noticed this infection in Germany. In Iraq a Pasteur institute was established at Bagdad. In this area anthrax, cholera, diphtheria, dysentery were of frequent occurrence. Leishmaniasis (Bagdad boil) is very common in native children. Malaria, plague, sand-fly fever, and bilharziasis were also common. Thus Iraq provided an interesting field for a pathologist. There were 11,544 men in the command and eight laboratories were provided.

Dental Treatment.

Dental treatment of the recruit began in 1906, when each otherwise fit recruit might have 20*s.* worth of dental work done on him if his dental condition thereafter would allow him to be accepted; by this method 1700 recruits were gained in 1907. Whole-time dental surgeons were required in the war, and were given commissions in 1915. At home during the war 70 per cent. of recruits required some dental treatment. An Inspector of Dental Services was appointed in 1918, and the Army Dental Corps was formed in 1921, to secure for the troops a high standard of dental service and thus reduce wastage. The dental officers were sent to the recruiting depôts. To simplify the grading of dental fitness points were given for all teeth in the upper jaw which were in good functional opposition to teeth in the mandible. Two points were given for each really sound molar, and one point for other teeth. Each tooth counted had to be sound or reparable. The maximum was 22, and no one whose total score was below 11 was received. During 1921, 82 per cent. of recruits required dental treatment and 81 per cent. of these got it. Lectures on oral hygiene are given to the troops; the new recruit is very readily teachable in this respect, and the majority of soldiers now clean their teeth daily. The proportion of teeth saved is continually rising; in 1920, 53 per cent. were conserved, in 1921, 59 per cent., while the number of extractions is falling. Scaling and treatment of infected gums and mouths are also done.

DEVONSHIRE HOSPITAL, BUXTON.—The sum obtained at a bazaar held recently in Buxton in aid of this hospital amounts to £8500. Money is still coming in, and the £10,000 necessary for the payment of the debt on the new extensions of the hospital will be realised.

INDUSTRY AND MEDICAL SCIENCE.

A WEEK-END CONFERENCE.

THE DOCTOR AND THE PSYCHOLOGIST IN INDUSTRY.

THE Institute of Industrial Welfare Workers held its annual Conference at Swanwick on Sept. 26th to 29th, when the above subject was discussed. Over 200 members were present, representing about 100 firms.

Dr. C. S. MYERS (Director of the Institute of Industrial Psychology) opened the discussion at the first session with a paper entitled

What Psychology Can Do for Industry.

He explained that the subject was too vast to treat as a whole, and he proceeded to describe certain points where psychology was actually doing valuable work for industry, illustrating his remarks with numerous lantern slides. Dealing first with the "work-curve," he described it as being as important to the industrial psychologist as a heart or pulse tracing is to the physician. After laboratory experiments on work-curves obtained under various conditions, similar investigation was carried out in certain factories and it was found that these curves were influenced by many factors. With practice, for example, a work-curve goes up while with fatigue it tends to fall, and if the curves be examined in detail other features become apparent. There is, for example, a definite spurt at the beginning of the day and a similar spurt at the end—spurts which are not necessarily conscious efforts. It was further found that if a person is taken away from his work for a short time he takes a certain period to "warm up" on his return. He passes through an "incitement" stage which is to be distinguished from the lower work-curves obtained after longer periods of absence from work which are due to lack of practice. By a study of a series of these curves it is possible to pick out those giving the best results and the work is then arranged accordingly. Dr. Myers next dealt with the influence of "rest-pauses." Work-curves were obtained showing higher levels after rest-pauses had been introduced. In one factory a 3 per cent. decrease in time worked, due to rest-pauses, led to a 5 per cent. increase in output. Pauses associated with change of work in another factory gave rise to a 14 per cent. increase in output and the workers were very appreciative of the better conditions. This aspect of the subject had been scientifically studied in the laboratory and the effect of varied occupation was strikingly shown. The "ease" of movement in occupation was next discussed. Too much stress in the past has been laid on the speed and extent of movements in mechanical tasks, but it had now been shown by experiment that "ease" of movement is the important factor. In one investigation an increase of output amounting to 35 per cent. had been attained simply by enabling certain work to be done with greater ease, and the workers themselves were struck with the lessened fatigue felt at the end of the day. Quality of work is also an important subject, and investigations had been carried out as to the reasons for spoilt work. In connexion with certain tea-shops breakages were markedly reduced (a 70 per cent. reduction in the breakages of cups, for example) by a study to ascertain how, why, and where breakages occurred followed by remedying of certain defects in the system of waiting. With reference to fatigue it had been discovered that the greater the skill of a worker at a particular job the less fatigue he experienced, and this was largely due to the fact that in the case of the less skilled worker "rhythm" breaks down earlier. Although it has frequently been shown that moderate decrease in working hours led to an increased output, the effect of excessive decrease in the number of working hours was to diminish the hourly output. This, it was suggested, is possibly due to loss of "incitement" caused by a long period of absence from work, over, for example, a long week-end. In observing the effect of decreasing the hours of work on the work-curve the results are not always immediate, often as much as three months is necessary to get the full effect. Dr. Myers next dealt briefly with vocational psychology, showing the importance of psychology in vocational guidance —choosing the best job for the individual; and in vocational selection—choosing the best individual for the job. Tests for special and general intelligence could be combined with the usual interview.

An interesting discussion followed in which the importance of the welfare workers who live in the atmosphere of the factory and in close touch with the workers themselves was emphasised.

At the second session Dr. W. F. DEARDEN opened the discussion on

What Medical Science Can Do for Industry.

He pointed out that we had reached a stage where manufacturers were at last beginning to realise what medical science can do for industry. The war had hastened this state of affairs, for the importance of the health of the worker in relation to output had been forcibly realised in connexion with munition work. Despite this the full significance of what medical science can do for industry has not been completely grasped, and the force which industrial welfare can exert will greatly help in driving this home. Dr. Dearden said that the foundations of the relation of medicine to industry were laid 200 years ago by Ramazzini, of Padua, who held very definite views which he expounded in a famous treatise. This Italian doctor had in his mind several basic principles which still held at the present day. He understood that the worker must be studied as a human machine, he realised the importance of cleanliness and ventilation. A century elapsed before his work was supplemented and nearly two before industrial hygiene became a properly defined branch of medical science. The study of the human machine could be undertaken by the physiologist and by the pathologist. The physiologist has to discover how bodily powers react to occupational conditions, and by suitable adjustment of these conditions he gets a maximum of output without waste of energy. Fatigue in its physiological aspect must also be dealt with so that no energy expended is unproductive. In the present position of trade the medical profession had a very definite function, and it can do its share towards putting industry on its feet. Dr. Dearden referred to the results of the advent of the industrial physician in America, where special courses of training exist for this branch of medical science. While industry is not quite on the same plane in this country it appears, nevertheless, that purely from an economic aspect industrial medicine, if properly applied, could bring about a tremendous annual saving. Dr. Dearden quoted Prof. E. L. Collis, who assesses the total possible saving to industry at £140,000,000 a year. The pathologist studies the morbid effects, local and general, brought about by fatigue. By the scientific study of industrial diseases, such as anthrax, for example, he has in the past done a great deal to cut down the incidence of these disorders. Ramazzini insisted in his book that the health of the workers must be studied in the workplaces themselves, and the fact that the earliest factory inspectors appointed in this country included a medical man was a very important one. With the advent of the certifying surgeon there was an increasing tendency to regularise employment according to physical fitness and the returns of these surgeons showed a gradually increasing percentage of rejections since they were introduced. The certifying surgeon acquires a great deal of knowledge of the factory and the processes carried on which should help him considerably in cases he has to deal with under the Workmen's Compensation Act. Dr. Dearden referred to the valuable work done by the medical inspectors of factories, and regretted that there were so few to do the large amount of work on industrial hygiene which was necessary. He urged that the State should employ more. Employers had their obligations, moral as well as legal, with regard to welfare work, and they had already done a great deal. He pleaded for a greater uniformity in the examination of young persons, and suggested that entrance and periodical medical examinations were desirable. The question of the examination of adult workers was more controversial, but it would be a great asset to have a health record of all the workers as long as this did not arouse suspicion amongst them that an entrance medical examination, for example, would have a deleterious influence on their engagement. Dr. Dearden pointed out how the hygienic requirements of the workers had been studied by medical science in relation to cleanliness, ventilation, humidity, lighting, and such like. He concluded by emphasising the importance of a knowledge of the occupation of a patient to his doctor, and urged that industrial medicine be made a compulsory part of the medical curriculum.

In the discussion which followed, the importance of the medical supervision of all workers and especially of adolescents was emphasised, and a plea was urged for a more satisfactory linking up with the school medical service.

At the third session the subject for discussion was

Accident Prevention: the Psychological and Physiological Aspect,

and this was dealt with from the *psychological aspect* by Dr. Millais Culpin. He began by pointing out that to say that accidents were due to carelessness, inattention, and so forth, did not go deep enough. There are certain people who are particularly susceptible to accidents, and this personal factor should be investigated to see what particular characteristic was associated with this susceptibility. Dr. Culpin then described the heterogeneous group of so-called "nervous" diseases, including neurasthenia, nervous breakdown, &c., and pointed out that common as these complaints were they rarely received investigation, although half an hour's talk would often clear up the trouble. That the "anxiety neurosis" may be associated with the occurrence of accidents was strikingly shown by a description of several cases where a definite pathological fear was present in individuals to whom or through whom accidents occurred. Dr. Culpin said that in the investigation of accidents, the expert psychologist was seldom called in, yet his evidence would be most helpful. The fear or anxiety present in these cases was not necessarily conscious, and he quoted a case in which unconscious remorse had led to the "self-infliction" of an accident in a perfectly unconscious manner. The presence of psychoneurotic symptoms in certain workers should lead one to suspect that they are susceptible to accidents, and welfare workers could help greatly by gaining the confidence of these people and listening to their troubles. Certain characteristic cases were mentioned, such as workers who cannot bear being watched, workers who are afraid of their machines, workers who rush at their jobs, and such symptoms should suggest to the intelligent welfare worker that these subjects required helpful treatment.

Dr. H. M. Vernon (Industrial Fatigue Research Board) next dealt with the *physiological aspect* of accident prevention, and he stated that accidents could be largely prevented by maintaining the workers in the best of health and under the best factory conditions. This is somewhat difficult to prove, but certain aspects had been particularly investigated. The importance of lighting was one example. Accidents were more common in factories during the winter months when artificial lighting had to be used more than in the summer. In America three times more accidents occurred on night shifts than on day shifts in one large steel yard, although factors other than lighting probably entered into consideration. The question of fatigue was an interesting one. Does the moderate fatigue of the ordinary day's work predispose to accidents? It was found that the frequency of accidents increases gradually during the day, and another factor in this connexion was probably the boredom experienced towards the end of a day's work. Lack of experience was another potent cause of accidents, and Dr. Vernon suggested that a period of training on fool-proof machines might prevent this. The speeding-up of production increased the occurrence of accidents both because quicker movements were generally clumsier and because increased speed gave rise to increased fatigue. Temperature was another factor: a certain optimum temperature—in one factory 69°—showed a minimum occurrence of accidents. Below this cold entered into the problem and acts by decreasing manual dexterity, while excessive heat probably acts indirectly and is partly psychological. The effect of the introduction of a cooling plant at the bottom of a mine in Brazil was cited as a striking example of the importance of correct temperature. Humidity was also important, especially in coal-mines where it was usually excessive, and where the ventilation in general was shockingly bad. The comfort of the worker demands attention, for the uncomfortable worker is more liable to accidents, and in this connexion the question of clothing, the provision of changing and bathing accommodation were all discussed. Lastly, Dr. Vernon referred to the general health of the worker and its relation to accident occurrence.

A good discussion followed in which other points, such as the presence of excessive dust on the floors of factories and the state of untidiness, were mentioned as prevalent causes of accidents.

General Discussion.

At the fourth session a general discussion of the subject took place. Mr. F. N. Epworth opened from the employer's point of view. He welcomed the advent of the psychologist in industry, but pointed out that progress must be gradual. Welfare workers can help by preparing the ground. This is very necessary, as innovations are viewed with distrust by the employer and worker alike. With regard to the doctor in industry, Mr. Epworth gave his experiences which, he said, had been unfortunate. He complained that the medical officer often only came near a factory to collect his fees, that he never saw the work being done, and he often never saw the workers he was supposed to examine. He strongly supported the suggestion that doctors should get to know the actual conditions of factory work.

From the workers' point of view, Miss Irene Pickup (Messrs. Rowntree) explained that psychology was not popular with the workers. They did not understand it, and they were prejudiced against it, associating it with "speeding-up" and "increased output" and other phrases of American origin which are cordially disliked. It was difficult for the worker to understand that the psychologist came into industry to help him. Miss Livingston spoke from the welfare workers' point of view, and said that the psychologist was most welcome because he could put a scientific case for decreased hours, rest-pauses, &c., and he helped to convince the employers. She was disappointed that no mention had been made of what medical science could do for industry in the future, for example, in dealing with such conditions as anæmia, gastritis, headaches, and neurasthenia, all of which were widely prevalent in the factories. Dr. M. G. Sheldon (a works' doctor) expressed her opinion that many of the disorders mentioned above were the result of faulty habits among the young workers, and could be reduced by educational methods. Dr. Culpin pointed out that so-called gastritis might be the physical manifestation of a neurasthenic condition, and pleaded that fears and grumbles among the workers called for just as much attention as accidents and anthrax, for example.

Numerous speakers gave interesting contributions from other points of view.

THE INTERNATIONAL DENTAL EXHIBITION.

THE International Dental Exhibition, which closes to-day (Friday), was opened at the Imperial Institute, University of London, South Kensington, on Sept. 29th, under the auspices of the Incorporated Dental Society. While the exhibition enabled the individual dental practitioner to keep himself in close touch with the latest improvements, methods, and equipment pertaining to his calling, it demonstrated at the same time the admirable response made by British firms to the demands of a specialty which plays so important a part in preserving the health of the people. During the week a series of lectures were given on various techniques and mechanical processes connected with dentistry and its practice. An important conference was also held at which the relation of the dental profession to the National Insurance Acts was discussed in all its bearings.

The Exhibits.

Two of the largest exhibits were those of Claudius Ash, Sons and Co., Ltd., 5–12, Broad-street, Golden-square, London, W., and De Trey and Co., Ltd., of London, Melbourne, Paris, Milan, and Madrid. The double cylinder "Empire" chair of the first-named firm attracted a great deal of attention. It is beautifully made and finished in a variety of enamels and coverings, with spring-balanced back and non-slip locking device on the arms, and while comfortable for the patient is equally convenient for the operator. The exhibits of this firm included a large variety of artificial teeth, instruments, and all the paraphernalia that the dentist requires in his surgery. The stall of De Trey and Co., Ltd., also attracted marked interest by reason of the fine display of their well-known Anatoform teeth specially designed to enable the practitioner to minister to the æsthetic demands of the patient while giving him or her at the same time teeth of practical utility.

Another interesting exhibit was the "Rayway" dental combination, Norman Rayne, 48, New Cavendish-street, London, W., an entirely British chair unit comprising hot-air syringe, mouth lamp, cautery, root canal dryer, electric compressor, motor converter, and other devices which add to the speed and comfort of a dentist's work; while the Raylim dental X ray outfit, X Rays, Ltd., 11, Torrington-place, London, W.C.; the Sunic X ray dental equipment, Watson and Sons, Sunic House, Kingsway, London, W.C.; the dental cabinets of C. J. Plucknett and Co., Ltd., Poland-street, London, W.; and the perfectly balanced chair made by the Dental Manufacturing Co., Ltd., Alston House, Newman-street, London, were the centres of many inquiries.

The Midland Dental Manufacturing Co., Ltd., 1, Needless-alley, Birmingham, and Mount Pleasant, Liverpool, showed an ingenious instrument called the Rahinator, designed to convey Rahinol, an antiseptic and anæsthetic, to the bur while in use. It consists of an attachment containing a small heating coil, and a detachable internal cylinder for holding the fluid, to which is screwed a fine flexible tube for conveying the fluid drop by drop. Close by, at the stall of the Birmingham Dental Supply and Manufacturing Co., were to be seen dental equipments for the surgery in large variety, while special notice was invited by the wide display of dental requisites of Gould and Co., Agol House, Mount Pleasant, Liverpool, including their "Never-Snap Bristles." Kodak, Ltd. (X Ray Department), Kingsway, London, W.C., had an attractive exhibit of their photographic material for dental radiography, and Parke, Davis and Co., 50–54, Beak-street, London W., showed a very attractive assortment of hypodermic cases for dentists and also their well-known tooth-paste Euthymol. Among other firms displaying dentifrices were Kolynos Incorporated, Chenies-street, London, W.C., whose well-known dental cream, which is entirely free from grit, has the following formula: Calcium carbonate, 21·00; soap, 25·50; thymol, 0·25; benzoic acid, 0·30; saccharine, 0·50; oil of eucalyptus, 1·75; oil of mint, 1·90; glycerine, 27·00; alcohol, 21·80; the Pepsodent Co., 42, Southwark Bridge-road, London, S.E.; and the Crown Perfumery Co., Ltd., New Bridge-street, London, E.C., who showed Corodenta for dental plates and artificial teeth, and Crown tooth paste, which has a pleasant lemon flavour.

Space does not permit us to mention the whole of the 40 or more exhibits, most of which showed merit, and indicated by comparison with previous exhibitions the steady advance of dental science and practice.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Poor-law Medical Appointments.

THERE has been for a long time grave dissatisfaction with the manner in which Poor-law medical appointments are made by local authorities. Family influences, friendships, political considerations often weigh more than professional ability. In some instances there is said to have been corruption of a grosser sort. It has been rumoured for some time that the Ministry of Local Government was considering the advisability of taking the power of appointing medical officers from the local authorities and giving it to a central appointments committee constituted mainly of representatives of the medical educational bodies. Such a plan, though undoubtedly an advance on the present system, is not approved unanimously by the medical profession, which has long demanded a national medical service with admission by competitive examination. The Ministry has now decided to try its plan in an experimental way in the Dublin Union. The affairs of that union are at present administered by paid Commissioners, the board of guardians having been temporarily suspended from its functions by the Government. The Ministry has written to the Commissioners suggesting that it would be greatly in the public interest if the Commissioners could establish a special selection board to appraise the merits, qualifications, and experience of applicants for the four vacancies for dispensary medical officers. The Commissioners accepted the suggestion, and decided to invite the registrars of University College, Dublin, of Trinity College, and of the Conjoint Board of the Royal Colleges to appoint a representative, each to act as a selection board, with the chairman of the County Dublin County Council as chairman. The profession will watch the working of this experiment with much interest.

Medical Reform.

At the summer session of the National Association of Insurance Committees, held last week in Dublin, the subject of reform in the public medical services was discussed. A report was received from a committee which had been previously appointed to inquire into the working of national health insurance and medical services generally. Among the recommendations of the committees which were adopted by the Association were the following: That the present permissive health legislation be made mandatory on local authorities; that tuberculosis be included in the schedule of infectious diseases compulsorily notifiable; that power be given to the tuberculosis medical officer of health to compulsorily isolate persons suffering from tuberculous diseases in cases where he considered isolation essential in the interest of public health, also the effective inspection of cattle in respect of bovine tuberculosis, the tuberculin test of the milk-supply, the effective inspection of cowsheds, power to committees dealing with tuberculous disease to afford preventive treatment to persons coming under their observation who, although not actually suffering from the disease, were in the opinion of the medical officer liable to contract it. Suggestions were also made for the provision of treatment-training colonies for civilian patients whose pre-treatment occupations were especially unsuited to persons suffering from tuberculous disease and the provision of adequate housing accommodation, and the making and enforcement of regulations against overcrowding.

The committee were in favour of the abolition of the Medical Charities Act, and recommended in substitution therefor the extension of medical benefit to insured persons and their dependents, the preparation of a register of persons whose lack of means or whose occupation rendered them ineligible for inclusion in the insured medical benefit scheme, power to the local health authority to employ district nurses or enter into arrangements with existing nursing associations, and to make available the services of district nurses in connexion with the various county health schemes.

Dr. Patrick T. McArdle has been elected Master of the National Maternity Hospital, Dublin. For some years he had been Joint Master along with the late Sir Andrew Horne. He is also gynæcologist to Jervis-street Hospital.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the principal statistics for 1923 of four county boroughs :—

Name of county borough.	Estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population. All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Death-rates per 1000 births. Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Oldham.. ..	147,500	17·8	16·0	1·2	1·3	4·6	45	112	5·0
East Ham ..	146,200	19·4	9·0	1·1	1·0	1·6	25	51	3·5
Huddersfield .	111,600	15·7	12·6	1·2	1·5	2·6	39	72	6·3
Warrington ..	78,910	22·4	11·0	1·4	1·0	2·7	26	75	7·3

Oldham.

Dr. J. B. Wilkinson says the past year will be notable for the beginning of a scheme for the clearance of the largest slum area in the town—viz., Smethurst-street area. This area, which has been regarded as insanitary for 20 years, covers 4·9 acres and contains 259 houses and a population of 1425 persons. On the other hand, it is difficult to see how rapid progress can be made, as, owing to house shortage, dilapidated and unfit houses cannot be closed. No municipal houses were erected during the year and the 42 completed by private builders are all of too large a type for the artisan population. The scarcity of houses enables those who engage in the trade of letting furnished rooms to charge exorbitant rents. Dr. Wilkinson gives one example of a derelict inn, let by the owners for £40 per annum, which yields a total annual rental for so-called furnished rooms of £408. The rents for the furnished rooms are paid in advance or the tenants are turned out. "In some cases which have come to my knowledge," says Dr. Wilkinson, "the rents have had to be obtained by immorality to avoid ejectment." The depression in the cotton and iron trades has interfered with the progress of the schemes for the substitution of water-carriage for pan-closets and ashbins for ashpits, but notwithstanding adverse circumstances a considerable amount of work in repairing property and remedying defects has been carried out.

During the year the Oldham and Rochdale corporations acquired the reservoirs of the Rochdale Canal Company; Oldham's share of the purchase includes two reservoirs and 1645 acres of gathering ground, and will eventually render available for domestic use over 2 million gallons of water per day. The renovation of the sewage works has provided some work for the unemployed. About two-thirds of the conveniences in the town are waste-water closets, and the cleansing superintendent's report shows that this class of closet gives a great deal of trouble through its liability to become blocked. There were no less than 5445 blockages cleared in 1923. None of the "graded" milks is on sale in Oldham, but two firms do a large business in "cleaned, sterilised, and bottled" milk. Dr. Wilkinson draws attention to the small number of females who seek treatment at the V.D. clinic for gonorrhœa. At the Oldham Royal Infirmary clinic there were only 19 females to 140 males under treatment for this complaint during 1923, and yet, as Dr. Wilkinson says, gonorrhœa "is the origin of a very large proportion of ailments from which women suffer." Antenatal work makes slow progress. There were only 61 cases at the clinic during the year and the births in the borough numbered 2617. Midwives notified 1946 births, and sent for medical aid in 289 cases. The usual fee charged by midwives is 35*s*., and occasionally the fee is £2.

East Ham.

Dr. W. Benton says a great deal of repairing work has been carried out at the instance of the sanitary inspectors, but that "in the Little Ilford ward many people are living under unsatisfactory conditions owing to the urgent need of further housing accommodation in the borough." East Ham has no maternity home, but the council occasionally pay for the accommodation of patients in homes at Plaistow and West Ham at the rate of 7*s*. per day. Six cases were so dealt with during 1923.

The school report indicates many needs, though Dr. Benton tells us that the pseudo-economic barrier is gradually disappearing and that the advantages of preventive and early curative treatment are becoming more generally recognised by the education committee. Dr. Benton describes the scheme which has been adopted for coördinating the municipal medical services. The committee has now decided to abolish the obsolete desks to which Dr. Benton drew attention in his 1912 report. Verminous conditions have not improved; in fact, the number of children with head vermin was greater in 1923 than in any of the three preceding years. The aural surgeon, Dr. G. C. Chubb, points out that half the ear cases are sent to him for deafness and half for discharging ears, and that among the latter group it is chiefly a question of preventing serious complications, as only a few show "marked improvement in hearing." He goes on to emphasise how much easier is prevention—by maintaining clear nasal passages and by dealing with infected adenoids and tonsils. The accommodation for the school dental clinic is again reported as very unsatisfactory and the dental staff is quite inadequate to deal with the needs of the children. Arrangements for the education of physically defective children are badly needed. Thus there were 552 such children in 1923 "for whom no adequate treatment, either in the form of an open-air school or a physically defective centre, has been carried out with the exception of the 26 children admitted to the Ogilvie School of Recovery at Clacton-on-Sea." The arrangements for dealing with mentally defective children are also inadequate.

Huddersfield.

Dr. S. G. Moore reports that 233 new houses were completed during the year, 98 by the corporation and 135 by private enterprise. Of the latter 97 were suitable for members of the artisan class. During the five years previous to 1914 the average number of new houses completed annually was 320, but during the five years preceding 1920 the number dropped to 47. The corporation have a scheme for building 1500 houses, and have built or nearly completed 600 during the last five years. In March Mr. John McKinna, F.R.C.V.S., was appointed veterinary inspector to the corporation. Of 53 samples of milk submitted for bacteriological examination, seven caused tuberculosis in guinea-pigs. This may be an under-statement of prevalence, as 30 of the 106 guinea-pigs inoculated died from blood-poisoning before the period necessary for the development of tubercle had elapsed.

No applications for selling "graded" milk have been received. A case of mixed milk deficient in fat led to the taking of samples from individual cows in the herd. The mixed milk of the herd on Feb. 15th showed a deficiency of 6·6 per cent. of fat, and the milk of three individual cows showed deficiences of 10 per cent., 20 per cent., and 40 per cent. respectively. The matter was ultimately referred to Mr. McKinna, who took a sample of the mixed milk on May 28th, which was found to contain 4 per cent. of fat and 9·25 per cent. of non-fatty solids. Midwives attended 721 of the 1728 births alone and 530 with a doctor. In 148 of the latter the midwife summoned medical aid, and in the remaining 382 instances the doctor was engaged beforehand. Huddersfield has no antenatal clinic, but has had in operation since 1916 a voluntary system of notification of pregnancy. Each expectant mother is visited and revisited as necessary by women doctors employed by the corporation, and the same practice is observed with notified births. The notifications of pregnancy received in 1923 numbered 579, or about one-third of the total births. Three home helps are employed to take over the household duties in the homes of maternity cases, and also two charwomen for washing and heavy cleaning. One pavilion of the Mill Hill Sanatorium for Infectious Diseases is equipped as a maternity ward of 12 beds, and receives cases when the home accommodation is unsuitable for the confinement.

Warrington.

Dr. G. W. N. Joseph tells us that the housing subcommittee select their tenants almost entirely on the urgency of the hygienic conditions under which the applicants are living. At the end of 1923 the waiting list of applicants numbered 1575, including 738 living in overcrowded houses and 171 mostly employed in Warrington, but unable to live there owing to the house shortage. Dr. Joseph gives particulars of the weekly rentals of the corporation houses :—

Wooden huts, with two bedrooms, kitchen, scullery with copper, larder, coal store, and w.c. ; 20 at 5*s.* 6*d.* + 4*s.* rates ; 20 somewhat smaller at 5*s.* + 2*s.* 4*d.*

Six concrete houses (on Dorman Long system—cost £850 each) at 9*s.*+6*s.* 1*d.* rates. These houses have sitting-room, kitchen, scullery, larder, coal place, and w.c. on ground floor, and three bedrooms and a bathroom on first floor.

Brick houses : 39 "Type B" with accommodation similar to Dorman Long houses, 9*s.* 6*d.*+7*s.* 4*d.* rates ; 17 "Type A"—i.e., without the sitting-room, at 8*s.* + 6*s.* 1*d.* rates ; 73 "Type A"—19 end houses at 13*s.* 11*d.*, and 54 inner houses at 12*s.* 11*d.*, both inclusive of rates ; 12 "Type A," completed last year, at 12*s.* 11*d.* inclusive.

There are still a considerable number of houses in the borough which ought to, but cannot, be closed. Seventy-two tenants of corporation houses have received permission to take lodgers. Much irritation is provoked among homeless people by the sight of empty houses retained empty "for sale with vacant possession."

The accommodation at the maternity home was much appreciated. There were 256 admissions, and additional accommodation is needed. Three Cæsarean sections were performed ; all the mothers made good recoveries and there were two living children. Provision is needed for the treatment of surgical tuberculosis. The new recreation hut at the sanatorium for pulmonary tuberculosis was completed during the year, and has been provided with a first-rate billiard table, a piano, a gramophone, and seating accommodation through the generosity of Lady Greenall. Ten patients were treated with tuberculin, but the results were not encouraging. Patients who give a history of chronic nasal catarrh are inoculated with stock anti-catarrh vaccine. Several tuberculous abscesses have been successfully treated by aspiration, injection, and exposure to sunlight. Dental treatment is only available for ex-Service men. Of 84 samples of mixed milk, representing the milk of 1200 cows, no less than 10 were found to contain tubercle bacilli. As the result of following up, eight cows which were giving tuberculous milk were found and dealt with.

SCHOOL MEDICAL SERVICE.

Leicestershire.

Dr. T. Robinson reports that the elementary school population here is about 36,000, and of these between ten and eleven thousand were medically examined, and 11·6 per cent. were found to require treatment. Dr. J. B. Dalton, the assistant school medical officer, reports that the number of children with enlarged tonsils and adenoids has decreased. He finds that parents questioned six months after the operation are of opinion, with few exceptions, that there is an improvement in the "physique and alertness" of the child. From the teacher's point of view the results have, on the whole, not come up to expectation. No numbers are given, but "the following up of cases of tonsils and adenoids operated on shows (*a*) general physique is first to benefit by the removal of these defects, (*b*) mental capacity is slower to benefit and is not so marked as in the case of bodily physique."

Northampton.

The borough medical officer of health here is now school medical officer in charge with one assistant and a whole-time school dentist, who acts after school hours as dental officer to the maternity and child welfare section. Most of the work dealt with during the year by the public health department, owing to the changes in the staff, has been of a routine character. Dr. J. D. McCrindle urges the necessity for open-air education. "There are many debilitated, anæmic children, often under-nourished, who readily fall victims to subsequent tuberculosis or other communicable disease who can get little real education in the ordinary school, and, apart from the effect on their health, public money is wasted in the attempt to educate them thus." Dr. J. H. Mason, assistant school medical officer, pleads for special classes for dull and backward children for whom at present no provision is made. He also deplores the tendency to widen the scope of special schools for mentally defective children by admitting low grades of mental defect. Altogether, between five and six thousand children were examined ; 3000 of these were routine examinations, and nearly 19 per cent. required treatment for physical defects apart from dental condition.

Northamptonshire.

The school medical work was much interrupted here owing to changes in the staff. Dr. C. E. Paget, who succeeded Dr. J. H. Mason as school medical officer in May, 1923, reports that the result of the appointment of a whole-time demonstrator of physical training is becoming apparent in the improvement and modernisation of the physical training methods now in use in both day and evening schools. Classes for teachers are being held throughout the county. The total number of children examined in the code groups was 2420 of a total school population of 27,646. Cleanliness amongst the children seems to have increased. Dental defect appears from the figures to have increased, but the group examined was aged 6 to 8 years, always a period when dental decay is more prevalent.

Scarborough.

It is pleasant to record that Seamer-road Nursery School is again recognised by the Board of Education. While this school was receiving no grant certain kind individuals in Scarborough supported it entirely out of their own pockets. The number of children on the school register at Seamer-road is 62. At the Friarage nursery class there are 74 children. Dr. C. J. W. Tatham is firmly convinced of the real value of these schools, and suggests that though in their present form they are expensive, the nursery school ought to be developed. The school clinic is utilised twice a week for infant and child welfare work, and the school medical inspector is in attendance. The total number of attendances during the year was 3498. Ringworm of the scalp occurred in 44 children, as against 35 in 1922, a larger number than is common in other areas with a similar school population. Dr. Tatham suggests that possibly ringworm attacks fair-haired oftener than dark-haired children, and that this larger number is due to the higher percentage of fair-haired children on the north-east coast than in other parts of England. Of children recommended for dental treatment 82 per cent. obtained it. There is no doubt that the high percentage of clean mouths got in this way will materially reduce the number of victims of toxic diseases, such as rheumatism, in later life.

Stockport.

Altogether 7398 children were examined, and of the 4759 who came under the code groups 25·6 per cent. were found to require medical treatment. At the central school clinic, open daily, and a branch clinic, open once a week, nearly 12,000 attendances were made by just over 3000 children. Children in Stockport are recommended for free meals by the school teachers, attendance officers, and medical officers. The children attend for breakfast and dinner five days a week, on Saturday they have dinner only. The average number of children attending the leading centres for meals was 80. In 1922 it was 103. Dr. A. G. Jenner reports that the food is appetising and much appreciated by the children; the cooking and serving are also good.

Torquay.

A marked reduction in the amount of uncleanliness, with a similar decrease in the number of cases of skin disease, is recorded. Dr. T. Dunlop states: "For the first time since the war these diseases would now seem to be completely under control." There were 42 cases of ringworm, 36 of these being scalp affections. These were treated to such purpose with calomel and iodine that only four cases remained on the books at the end of the year. Attendances were not lost, as all those children attended school wearing washable caps provided by the authority. Arrangements have now been made for ringworm cases to obtain X ray treatment at the Torbay Hospital when necessary. A register of all dull and backward children is kept, and the children carefully examined as to mental and physical condition. It is unfortunate that for financial reasons the very necessary scheme for starting a class for these children at the open-air school has had to be abandoned. Dr. Dunlop gives credit to each of his assistants for their separate contributions which comprise the full annual report.

Warwickshire.

Much useful work is being done in the 31 voluntary infant welfare centres. During the year 23,435 attendances of children between 1 and 5 years of age were made at these centres, and a total of 17,762 examinations of school-children were made. The services of an additional dentist have been secured, and it is now hoped that dental treatment will be available for all children of from 6 to 8 years of age. Medical inspection during the year has revealed the necessity for an immediate increase in the accommodation in many of the schools in the more populous parts of the country. The strength of the health visiting staff was reduced by two in 1920, and Dr. A. Hamilton Wood suggests that a return to the former strength of 17 instead of 15 as at present is desirable. The standard of physical training in this county has improved largely owing to the increased interest among teachers in this branch of the work. Mr. P. R. Marsh, the county organiser of physical education, refers to the unsuitable clothing and footgear worn by so many of the children during games and drill. It would be more pleasant if this report were published in a form less unwieldy.

West Riding of Yorkshire.

The area of the West Riding for purposes of elementary education consists of over a million and a half acres, and has a school population of nearly 193,000. Dr. J. R. Kaye says: "The school population is altering slightly in distribution. The development of the coalfields around Doncaster is causing an influx of population to this district, and throwing some strain on existing schools." He is concerned, too, about the housing needs of this area, which are not being adequately met. Another matter which is also causing great concern is the inadequacy of specialist staff here. "The growing arrears of children who have been recommended for further examination of the eyes with a view to getting glasses cannot be contemplated with equanimity . . . . the problem facing parents of these children is of some magnitude; railway fares and refreshment, loss of a day, cost of getting someone to look after the children remaining at home, and if, as not infrequently happens, the examination is not completed and the prescription for glasses issued on the first visit there it has to be repeated." Truly, the penalties for living in the rural districts of the West Riding are absurdly heavy. Dental treatment also in many districts is unavailable. Although it is evident that the demand for these amenities may require stimulating in a county where "the head teacher instituted a sewing class in which the girls under the head teacher's dictation replaced safety-pins and other emergency devices on their own clothes by buttons, tapes, or hooks-and-eyes, and the parents took them off and sent the girls back to school without them!" An investigation was made by Dr. G. W. Fleming into the question of malnutrition in the Wakefield area. He worked on a weight and height ratio. Taking 2000 children he found that 30·8 per cent. were 10 per cent. or more below the average. A fairly large percentage was undersized while retaining the weight-height ratio. The malnutrition found is attributed largely to an ill-balanced diet which is deficient above all in accessory food factors or vitamins. The report also contains an interesting article on "arrested caries." It is unfortunate that the general medical profession in the West Riding coöperates so little in this preventive work. Indeed, occasionally the school medical service has had to face not only a lack of coöperation, but an attitude which Dr. Kaye describes by stating that "it would be going too far to suggest it was wilful obstruction."

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 20TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 53; scarlet fever, 1688; diphtheria, 886; enteric fever, 103; pneumonia, 449; puerperal fever, 38; cerebro-spinal, fever 8; acute poliomyelitis, 29; acute polio-encephalitis, 3; encephalitis lethargica, 39; typhus fever, 1; trench fever, 1; dysentery, 5; ophthalmia neonatorum, 132. There were no cases of cholera or plague notified during the week. The case of typhus was again from St. Helens.

Deaths.—In the aggregate of great towns, including London, there were 6 deaths from enteric fever, none from small-pox, 8 from scarlet fever, 21 from diphtheria, 7 from measles, 21 from influenza. In London itself the diphtheria deaths numbered 8 and the deaths from infantile diarrhœa 28. Another death from typhus was registered from St. Helens.

METROPOLITAN HOSPITAL.—The Metropolitan Hospital, Kingsland-road, which has 137 beds and ministers to the needs of one of London's poorest districts, is making an appeal for £50,000 in order to build a nurses' home and improve the casualty department. The Lord Mayor, Sir Louis Newton, President of the hospital, and Lord Howard de Walden, chairman, are organising the appeal, and special efforts will be made on behalf of the hospital in the district in which the hospital is situated, in the City, and in the West End.

Correspondence.

"Audi alteram partem."

WORKING FOR PROMOTION.

To the Editor of THE LANCET.

SIR,—The Director-General of the Army Medical Services is Sir William Leishman, professionally a bacteriologist, whose name has long been in the minds and mouths of the profession as the author of the Leishman stain and the discoverer of leishmaniasis, widespread throughout the world but unrealised until, like America, it was discovered. The Surgeon-General of the United States Navy is also a bacteriologist, Rear-Admiral E. R. Stitt, whose handbook is on the working bench of every laboratory. Thirty years ago we may fairly imagine these two young officers hard at work and indignantly commenting to their intimates on the neglect—opposition maybe—of superiors who could not realise the importance of the new science these young officers were learning and hoping to turn to profit for the Service. They did not sulk or throw up their hands and cease work as men with less conviction have been known to do. They stuck to their guns, their guns saved them, and now everything is in their power. There are junior officers now who feel neglected. Many of them have come from medical schools, where their talent soon began to shine out in that small, almost home-like area. They are now in a world which takes people to its heart slowly. Many of the juniors can dress their windows well, but which of them has the well-stored warehouse and can go on delivering the goods? It is for him that the Services are continually on the search. Who can say whether directors-general, 30 years hence, will be chosen from administrators, bacteriologists, operating surgeons, electric specialists, or some other branch, perhaps now unknown? One thing alone is certain. These prizes will not be for men who have drifted. Advancement will come to the man who does the work his abilities make him think the most important, does it thoroughly, does it hard, and does it long. His qualities must be proved in the furnace of affliction, or at least of strenuous opposition. But good work, done by an unselfish man with sympathy and helpfulness to those who are his associates, will rarely fail of its reward.

I am, Sir, yours faithfully,

Sept. 29th, 1924. OLD FOGEY.

THE TISSUE PATHOLOGIST.

To the Editor of THE LANCET.

SIR,—The letter of Dr. E. H. Shaw in your last issue reminds some of us of the days when the keenest minds amongst the young consultants were interested in the microscopical appearances of diseased tissues. Many improvements have taken place since then, both in the preparation and interpretation of histological sections, but it is still difficult sometimes to distinguish between tuberculous and syphilitic changes or to estimate the various degrees of malignancy presented by tumours which are on the border-line. The suggestion, therefore, of preserving, classifying, and cataloguing sections of doubtful nature is very valuable if it could be put in practice. It does not seem likely that any of the corporated bodies would devote time, space, or money to such an object, but it could well be begun in a little way as a beginning if someone would undertake the initial expense of a small laboratory attached preferably to one of the research associations which are at present doing good work.

Yours faithfully,

D'ARCY POWER.

Chandos-street, Cavendish-square, W., Sept. 29th, 1924.

DENTAL DRESSERS.

To the Editor of THE LANCET.

SIR,—Your favourable endorsement of the Derbyshire dental dresser scheme, which appears in THE LANCET for Sept. 20th, will be read with mixed feelings by many of your dental readers. For my own part I am definitely opposed to this scheme, and I know that many other dentists are of the same view, while the British Dental Association has always opposed the proposals of Dr. Barwise.

The scheme is put forward chiefly on the ground that there is a shortage of dentists. Is this a fact? As a teacher at a dental school I am in touch with a large number of recently qualified dentists, and I know that for every dental appointment, both part-time and permanent, there are large numbers of fully qualified applicants. This is the case even when the salary offered is below the standard which the British Dental Association regards as the minimum, and the advertisements for that reason are not accepted by the *British Dental Journal.* This does not look like a shortage of dentists. I suspect that the real reason is that the local authorities are unwilling to face the expenditure necessary to provide adequate treatment by qualified dentists, for in the abstract of the report of the school medical officer for Derbyshire there is the significant statement that "we cannot afford to employ dentists to do the necessary work, and if we could they are not available." With the assumption that there are not enough dentists available I have dealt. But even if the number of dentists increased, is there any likelihood that the Derbyshire authorities, or for that matter any other public bodies, would pay for the services of qualified dentists if they can get the work done by dental dressers under the supervision of a few dentists? It seems to me very evident that though this scheme is put forward under the specious guise of a temporary expedient, once it becomes established there is little chance of a reversion to the principle that dental work should only be done by qualified dentists, even although the number of the latter should be largely increased. In these days economy is a popular appeal, but cheap dentistry, like cheap medicine, is neither good for the dental profession nor for the public whose interests it exists to serve.

It is stated in the report of the Derbyshire scheme that there is no risk that these dental dressers might form a centre for the creation of a number of unregistered practitioners. When the scheme was first evolved by Dr. Barwise before the passing of the Dentists Act, 1921, the British Dental Association strongly opposed it partly on the grounds that it might provide a training ground for unregistered practitioners under public authorities. The passage of the Act has removed this danger for the present. It is, however, very significant that when the small amending Act of 1923 was passed conceding a reduction in the statutory age to certain ex-Service men, an attempt was made to introduce an amendment admitting these dental dressers to the prescribed examination established by the Dentists Act as an easy route to registration for those individuals who were practising without being registered. Can we be certain, therefore, that the danger has passed? In the event of any further amendments to the Act it is highly probable that were there in existence a large number of dental dressers carrying out work of the nature advocated by Dr. Barwise, that strong pressure would be brought to give them a legal status.

Already under the Mond scheme (Circular 1279) the Ministry of Health, in agreement with the Dental Board, has sanctioned the employment of dental nurses whose work is limited to cleaning and polishing teeth, applying or removing temporary dressings, and charting work under the direct supervision of the dental officer. But Dr. Barwise is not satisfied with this, and says bluntly that the employment of dental dressers under these conditions "is of no use to us." He presses strongly for permission for dental dressers to inspect and chart the mouth, to extract and treat temporary teeth, and to fill first permanent molars. In spite of the radiographs of fillings done by dental dressers and the testimony of various dentists, I am not convinced that this work can be satisfactorily performed as a routine measure by unqualified dressers. As dental surgeon to a large children's hospital, I am fully acquainted with the problems connected with the dental treatment of children, and in my opinion there is no branch of dentistry which calls for so much judgment and skill. Extractions even of temporary teeth and roots should in most cases be done under a local or general anæsthetic Is it suggested that the dresser should also do this? The filling of first permanent molars is a very important part of a school dentist's work, and yet it is suggested that this should be delegated to dental dressers "of matriculation standard" under the supervision, for what it is worth, of a qualified dentist. This is, indeed, putting back the clock of dental progress with a vengeance.

I feel certain that the dental profession as a whole will oppose these proposals of Dr. Barwise, and I trust that the Dental Board will not give their sanction to a step which I believe to be detrimental to the best interests of the public dental service.

I am, Sir, yours faithfully,

Wimpole-street, W., Sept. 24th, 1924. A. T. Pitts.

⁂ Mr. Pitts's reasonable claim that the dental profession can and should take over the whole responsibility for the teeth of school-children will be read with unmixed feelings of approval. At present the absence of such care in county areas is a menace to the health of the coming generation. For this reason it seems to us that any temporary expedient which is achieving good results should be regarded with indulgence.—Ed. L.

CHLORIDE METABOLISM IN RADIATION TREATMENT.

To the Editor of The Lancet.

Sir,—The paper on the above subject by Prof. A. T. Cameron and Dr. J. C. McMillan in your issue of August 23rd makes several references to work of ours recently published by you (The Lancet, 1924, i., 533), and we should be glad if you would allow us to make a few comments.

1. Cameron and McMillan make no reference to the normal variations in chloride metabolism, and they give the chloride excretion in their cases only for one or two days before the X ray treatment was commenced. Cases examined by us, in some instances for weeks before treatment was commenced, showed very wide variations in chloride excretion.

2. Three out of their five detailed cases were patients with gastric cancer. If the notable deficiency of gastric HCl in these cases be considered, it appears to us evident that the general Cl metabolism in similar untreated cases, or in such patients for a considerable time before treatment, would need to be analysed first before any reliable general deductions could be drawn as to the effect of radiation.

3. Their first two cases show very slight changes in chloride excretion—quite within the normal range of variation. Their third case had nausea but no sickness after salt feeding was started. The chloride excretion, however, remained low up to the twelfth day of such feeding. As the patient died three weeks after the last treatment it appears to us that no conclusions of value can be drawn from such a patient's terminal metabolic reactions. Their fourth patient had salt feeding, and no salt retention, and no sickness (slight nausea). This case would appear to us to be useful only possibly as a control. Their fifth patient frequently vomited after meals before the treatment began. (No analyses are given of the urine before the treatment.) He was worse after the second treatment; salt feeding was started, and was followed after five days by a sudden large chlorine excretion. That the coincident improvement in his general condition was due to the salt feeding, as the authors conclude, does not seem to us to be warranted, as improvement in any case might be expected a week after the last X ray treatment. Many more control examinations would seem to us to be necessary before the authors' conclusions can be substantiated.

4. They conclude, on the basis of urinary analyses, that there is "no production of acidosis." Blood analyses are essential for hydrogen ion and alkali reserve estimations. The authors do not refer to the valuable work of Whipple and others on this point, which our work seemed to confirm.

5. Our work was mainly done in the winter and spring of 1922–23, the literature was summarised to July, 1923, and our paper was submitted for publication before Cori and Pucher's paper on chloride retention had appeared. Hence no reference to it was made.

6. As to details of the X ray treatment given in our cases, where the word "intensive" was used that implied, as is generally understood, radiation with a tube activated at 160–200 kilovolts, and filtered with at least 0·5 mm. zinc or copper, and applied so as to administer approximately a "skin unit dose" throughout the area of evident or probable disease, including the associated lymphatics. We felt that full details of the 12 or so factors involved in X ray treatment would occupy more space than was justified in a non-technical paper. The X ray details given by Cameron and McMillan are indefinite. (What is meant by a "13 cm. port"?) The necessary factors are variable, or are not given. In considering metabolic changes the *essential* factor must be the "volume-dose," or "body-dose" as it has been called, the total of absorbed radiation. To give the dosage in electrical terms as milliampère hours, or otherwise indirectly as they do (e.g., 100 k.v. 4 mm. Al filter) gives neither an estimate of the superficial nor the depth intensities, from which the "volume-dose" (other factors also being considered) could be calculated. Correlation between "volume-dose" and metabolic changes would have so greatly enlarged the scope of our investigation (which was already taxing the limited resources of the biochemical staff to its utmost) that we had to leave this for future investigation by ourselves or others, and on a larger series of cases.—We are, Sir, yours faithfully,

E. C. Dodds.
J. H. Douglas Webster.

Middlesex Hospital, W., Sept. 24th, 1924.

THE DIAGNOSIS OF A HEALTHY HEART.

To the Editor of The Lancet.

Sir,—Dr. A. Graham-Stewart's letter in your issue of Sept. 20th seems to raise the old question of the correct definition of the term "functional." Taking simple paroxysmal tachycardia—Dr. Parkinson expressly excludes auricular flutter and fibrillation—to be merely a succession of extra-systoles either auricular or ventricular, a disorder in function of the heart would appear to be the best description possible for the condition. That extra-systoles themselves may have a prognostic significance when due to the irritability of fatigue in the presence of a definite cardiac lesion does not gainsay the fact that most people who suffer from them have nothing else to suggest heart disease. As Dr. Parkinson says, "These are not in themselves an index of heart disease, although they may occur along with it." Surely the same should be said of paroxysmal tachycardia, with, however, this additional factor in prognosis: that it does not do any heart good to beat for long at a rate of over 200. No one, of course, would apply the term "functional" to this condition in the sense that it is used by some neurologists in cases of hysteria and allied disorders.

I am, Sir, yours faithfully,

Harrogate, Sept. 24th, 1924. C. W. Curtis Bain.

CANCER AND SOME OF ITS SIGNIFICANT CHEMICAL REACTIONS.

To the Editor of THE LANCET.

SIR,—Cancer research during the past few years has been pursued with great diligence and has received considerable impetus from a number of different sources. In view of Sir George Beatson's most interesting letter, published in your columns of August 23rd, and also A. N. Currie's article on the Fat of Adipose Tissue in Malignant Disease,[1] a short account of the recent observations made in the Physiological Laboratory of King's College may not be out of place.

The large amount of yellow fat in the neighbourhood of a cancerous growth—e.g., in scirrhus growths, penetrating the tumour itself and incorporated with it, as pointed out by Beatson—is self-evident to those in the habit of dealing with such material. Further, Beatson[2] showed that a large percentage of this fat was unsaturated and suggested that the cause of the unsaturation was a local enzyme, which thus rendered the fat an easier pabulum for the growth. Currie, in his paper referred to above, shows that extractions of fat from healthy tissues have an average iodine value of 60·8, while those from fat adjacent to carcinoma have a value of 74·4. He also gives a feasible explanation of an oxidase-reductase system, which can readily be shown to exist in the connective tissue. This is in accordance with the well-known facts that adipose tissue is rich in a fat-splitting enzyme and in catalase.

Shaw-Mackenzie has shown that tissue lipolysis and utilisation of fats is defective in cancer. Furthermore, he suggested, so long ago as 1910, that the fatty acids, or their sodium salts, are important factors in the protective processes or induced resistance of the body. Rosenheim and Shaw-Mackenzie[3] showed that sodium oleate and other hæmolytic substances have the power of increasing lipolytic action; while cholesterol, on the other hand, inhibits the action of sodium oleate and other activators of lipase. Thus sodium oleate may not only be protective in itself, but may hold in check the inhibitory action of cholesterol in the body.

Whether the lipolytic deficiency, or the fact that the oxidase-reductase system is out of gear, or both these factors acting concurrently be the cause of the accumulated unsaturated fatty material in cancer is a question which further research will answer. That the oxidase-reductase system, a theory of whose mechanism Currie has outlined, plays by no means a negligible part receives support from the results of workers in widely divergent fields. Glutathione, discovered by Hopkins in 1921, and isolated by him from yeast cells and from various animal tissues, by virtue of its chemical structure, is a means of transport of hydrogen within the cell. Hopkins has shown that oxidation of unsaturated fats is readily catalysed by glutathione, and it can easily be shown, as Currie has done, that the tissues contain an oxidase. Further, von Fürth found in his work on the oil in the seeds of the sunflower and castor-oil plant that the changes which occur consist of an increase in saponification value and a lowering of the iodine value. The increase in saponification value indicates the formation of lower fatty acids from the higher ones; and lowering of the iodine value shows that the ethylene linkages have been destroyed during cleavage. A similar kind of action to that just described in the case of seeds takes place normally in the liver of a healthy individual. The higher fatty acids—e.g., stearic acid—are desaturated and cleavage occurs at the weak spot—viz., the ethylene linkage, giving rise to simpler fatty acids. Hence, it seems obvious that in cancer these reactions of desaturation and cleavage are in some way inhibited.

But the excess of unsaturation cannot wholly be explained in this manner. It has long been known that excess of lecithin occurs in the cancer cell. In addition to lecithin, the carcinoma cells are rich in cholesterol. Wacker has pointed out that the fat deposits in the subcutaneous tissues and mesenteries of persons suffering from carcinoma is no less than 66 per cent. greater in cholesterol content than the fatty deposits in normal persons. The iodine value of cholesterol is exceedingly high, and the large increase in iodine value which Beatson and also Currie have reported and which I, in collaboration with Shaw-Mackenzie, have also noted is probably due in no small part to increased cholesterol content. This increase in cholesterol content is not only found in the carcinoma cell and the neighbourhood of the cancerous growth, but extends to the serum of cancer patients. The increase in cholesterol in the serum is quite marked and has been exhibited in every case I have examined. Also preliminary qualitative experiments of bromine absorption in chloroform extracts of the serum indicate the increased unsaturation. This would be expected in virtue of the fact that cholesterol contains an ethylene linkage.

For the last 14 years Shaw-Mackenzie[4] has been working in this laboratory on the sera-diagnosis of cancer, and recently I have been inquiring into the chemical nature of the tests he has elaborated. Although, as yet, I have not succeeded in elucidating all the chemical factors, I am satisfied that there is evidence of increase of cholesterol in the serum of carcinomatous patients. It is not claimed that this is absolutely specific for cancer, but that it is sufficiently so to be of diagnostic value. It is not for me to discuss this aspect of the problem, but the foregoing evidence will justify the statement that there is considerable alteration in the metabolism of fats and lipoids occurring in the blood and tissues in cases of carcinoma. It must, however, be remembered that this increase in cholesterol may be primary, or that it may be secondary to the carcinomatous state, but as yet there exists no evidence that I know of pointing in any special direction, and unfortunately, it is a subject in which it is extremely easy to formulate hypotheses.

I am, Sir, yours faithfully,

H. GORDON REEVES, M.Sc., A.I.C.,
Department of Physiology, King's College, London.

Sept. 17th, 1924.

METASTATIC GAS GANGRENE.

To the Editor of THE LANCET.

SIR,—I was greatly interested in the case of metastatic gas gangrene reported by Mr. J. R. Learmonth in THE LANCET of Sept. 27th. About a year ago I had a somewhat similar case which I think is worth recording.

The patient was a male, aged 47, who had suffered from symptoms of duodenal ulcer for a considerable period. Operation was ultimately accepted by the patient after two severe hæmorrhages had occurred.

On opening the abdomen a large duodenal ulcer could be felt on the posterior surface of the upper half of the second part of the duodenum. The tip of the finger could be inserted with ease into the crater of the ulcer by invaginating the anterior wall of the duodenum. Posterior gastro-enterostomy was performed with some difficulty as the omenta were very fatty and the stomach small and high up. A rather badly damaged appendix was removed at the same time. Clamps were used in the anastomosis, but no undue traumatism occurred. For two days after the operation the patient was perfectly comfortable with no symptoms at all to cause the slightest anxiety; indeed, he promised to have a smoother post-operative convalescence than usual.

On the third day, about 56 hours after operation, he complained of a tight feeling in the right side of the chest, and two hours afterwards had a severe rigor. An examination of the chest revealed nothing at all. The temperature now commenced to swing and the pulse-rate to accelerate, and on the morning of the fourth day I found a small dusky area about the size of a sixpence on the front of the chest wall at about the level of the fourth costal cartilage and surrounding this a small area of slightly œdematous skin in which distinct crepitation could be obtained. Gas gangrene was at once suspected and with a syringe a few drops of serum were withdrawn in which the *B. welchii* could be demonstrated with ease. The area of œdema and discoloration rapidly increased in size and in 24 hours occupied a considerable area on the front of the chest. The abdominal wound remained clean and sweet throughout. The symptoms of intense toxæmia increased rapidly and in six and a half days from the operation the patient died, retaining his mental faculties until the end.

---

[1] Jour. Path. and Bact., 1922, xxv., 214.

[2] THE LANCET, 1911, i., 1560.

[3] Jour. Physiol., 1910, xl., 8, 12.

[4] THE LANCET, 1922, ii., 759.

This complication of gastro-enterostomy was quite unknown to me and caused me much heart-searching in an attempt to explain its occurrence. Unfortunately the case occurred in private practice and no autopsy was allowed. The wound remained perfectly sound throughout, and I do not think the infection came from this source. The catgut used was tested and found sterile. No abrasion was present on the patient to allow of the entry of the organisms. I was forced to the conclusion that the infection came from the intestinal canal where the bacillus has a normal habitat. Three portals of entry to the blood-stream are available if this is the case. First, the cut edges of stomach or duodenum at the anastomosis; secondly, from gut injured in the operation—e.g., by clamps—the organisms entering through an abrasion of the mucosa; thirdly, from the ulcer itself. I think the last alternative is the most likely in this case. The ulcer being injured slightly by the manipulation it received during investigation organisms could gain access to veins in its floor. Infection of the retro-duodenal veins thus occurring widespread infection by venous connexions is possible.

B. T. ROSE, Ch.M., F.R.C.S. Eng. & Edin.
Birmingham, Sept. 27th, 1924.

KING'S COLLEGE HOSPITAL.

SCHOOL OF DENTAL SURGERY.

To the Editor of THE LANCET.

SIR,—I notice that in the Students' Guide—Session 1924–25, printed in THE LANCET of Sept. 27th, no mention is made of the school of dental surgery at this hospital. The new school was opened last November by the Rt. Hon. F. Dyke Acland, M.P., Chairman of the Dental Board. I enclose a calendar of the school showing the requirements for admission. Communications should be addressed to the Secretary at the Medical School, King's College Hospital, Denmark Hill, London, S.E. 5.

I am, Sir, yours faithfully,
Sept. 29th, 1924. H. WILLOUGHBY LYLE, Dean.

HOP DERMATITIS.

To the Editor of THE LANCET.

SIR,—Following on the series of cases of hop dermatitis described by Dr. W. J. O'Donovan in THE LANCET of Sept. 20th, the notes of this case may be of interest.

Mrs. A. P., aged 40, attended the casualty department of the Miller Hospital, Greenwich-road, London, S.E., on Sept. 19th. A week after commencing hop-picking in Kent she developed a rash on her face, hands, and legs, and simultaneously her eyelids had suddenly become swollen. On examination a few days later there was still considerable œdema of the eyelids and a papular rash on the face and neck with an erythematous base, the rash causing a good deal of itching. On the backs of the fingers, hands, and wrists the rash had been at first papular, later becoming vesicular and pustular, and finally had formed crusts. Many weeping areas were present where the vesicles had been scratched. On the legs, however, the eruption was different, appearing on the anterior aspect of the leg as purpuric spots up to 1½ inches in diameter, round or with crescentic edges when several smaller patches had become confluent. There was a considerable amount of tenderness in these areas.

This case differs from those reported by Dr. O'Donovan in two respects: (1) The presence of a purpuric rash on the legs; (2) though the patient had been hop-picking in previous seasons, she had never before suffered any similar condition.

I am, Sir, yours faithfully,
C. J. STREICH, M.B. Adelaide, M.R.C.P. Lond.,
Sept. 29th. House Physician, Miller Hospital, Greenwich.

EPSOM COLLEGE REGISTER.

To the Editor of THE LANCET.

SIR,—Particulars for a revised edition of the Register are now being collected. Will those who have received forms kindly fill them in and return them to the sub-editors at once? Any old Epsomians who have not received forms should send their address to me without delay.

I am, Sir, yours faithfully,
7, The Avenue, Beckenham, Sept. 27th. H. F. LEE.

REPRESSION OF PAINFUL MEMORIES.

To the Editor of THE LANCET.

SIR,—I venture to suggest an explanation of the process by which painful memories are repressed—i.e., memories of painful experiences which have at some period of life (usually childhood) occurred to patients, and of which they were, of course, consciously aware. The explanation is based partly on observation on myself, partly on observation of a number of cases of war shock, and partly on the experiences of many friends and acquaintances whom I have questioned.

First, as regards my own personal experience. During the war, like many others, I underwent an experience which caused me intense mental suffering. On examining the course of mental events which followed this, I found that if anything occurred to remind me of the event in question, the immediate result was not the revival of the memory of the event itself, but the uprising of the same emotion of horror which it had originally caused, and that the memory of the event arose afterwards. Sometimes quite an appreciable interval separated the occurrence of the emotion from the rise of the memory—I could not bear to think of the latter and by an intense voluntary effort managed to drive it out of my mind and to think of something else. Within 48 hours a new phase commenced. When the emotion arose I was aware at once the memory would almost immediately arise. The occurrence of the emotion, in fact, acted as a danger signal, and I found that I instantly made a tremendous effort to prevent the rising of the memory, and to refuse to think of it. It was just like knowing that a repulsive picture was hanging on the wall, and refusing to look at it. In a very short time I found that I was able by this effort to hold the memory at bay, and so temporarily to repress it. The effort to repress afterwards followed with great regularity each time the motion occurred—so regularly and certainly that it became, I believe, a true psychical reflex act, and was always, I think, successful.

In a number of cases of war shock I found the same process carried out. I used to ask these soldier patients: "What happens when you are reminded of your horrible war experiences? I suppose they come before you very vividly." The answer was almost invariably, "Oh no, Sir, I feel just awful, but I never dare think of them," or words to that effect. The emotion clearly arose, but an immediate voluntary effort prevented the rise of the memory and, as in my own case, effectually locked it out. It will be noticed that these subjects were able to hold the memory at bay simply because they were warned of its approach by the emotion which preceded it. I have questioned numbers of people, and found that very many could recall some instance where the emotion preceded the occurrence of a painful memory.

I believe that we may state the following as a general law: "If the emotion caused by a painful experience is sufficiently strong, it always arises before the memory of the experience itself, when the subject is reminded of the latter." It appears to me that this law is responsible for the whole of the process of repression, and for the subsequent unpleasant sequelæ. In children (who are, of course, especially liable to repress painful memories) exactly the same chain of events, I believe, takes place when they are reminded of a painful or terrifying experience. The emotion arises first—acting as a danger signal—

and the memory is repulsed and held at bay just as in adults. But children are engaged in making every voluntary action which is often repeated automatic if they can, and what was at first a voluntary conscious act of repression, in their case rapidly becomes an unconscious and automatic one. The result of this process in the after-life of the child seems a fairly obvious one. If anything occurs to remind him of his painful experience, the emotion immediately arises, and at once causes the automatic repression of the memory which threatens to arise. The result is that the unfortunate individual is seized by some painful and often agonising emotion, which he is totally unable even to attempt to resist or combat, since he is utterly unconscious of its cause.

It is these emotions which form the symptoms induced by a repressed memory, and they may be, and often are, extremely serious. One of the commonest emotions met with in these cases is fear, and this alone may of itself give rise to other grave symptoms. I have seen the emotion of fear caused by a repression actually induce attacks of true epilepsy and catalepsy, and the number of different symptoms met with in various patients who suffer from repression is almost legion. But if the patient can be made to recall the actual painful experience (and this can often be done by means of even light hypnosis, or by some psycho-analytic procedure) the symptoms caused by the repressed memory vanish at once and permanently.

One is often asked, " Why does the recovery of the repressed memory cure the symptoms ? " I think the question is better put in this form : " Why do recalled painful memories do us no harm ? " It is certain that most of us can recall many painful memories, and that these memories produce no pathological effects. I conclude that remembered painful memories are harmless, probably, I imagine, because we can bring our judgment to bear on them. When the patient recalls the memory which caused his symptoms, it begins at once to behave like the rest of his remembered painful memories of life. Like them, it now does no harm, and produces no symptoms, and the patient is cured.

I am, Sir, yours faithfully,
HUGH WINGFIELD.

Rupert-road, Bedford Park, W., Sept. 26th, 1924.

MILK PROBLEMS.

To the Editor of THE LANCET.

SIR,—The leading article with this title in your issue of Sept. 20th opens up points of vital importance to national health. Taking milk as a whole the standard of purity in this country is very low indeed. There are a few enthusiastic pioneers in the industry, who, without compulsion, try to place a clean germ-free article on the market, but they are so few that their beneficent influence is negligible. It appears to me there are only two ways whereby the milk standard could be universally raised—viz., compulsion and education.

In regard to the former, if the Milk and Dairies Act, and the Tuberculosis Order, 1914, were put into force, great good would follow, and I think it is unfortunate that such an influential body as the Council of the British Medical Association should decline to bring pressure to bear upon the Government for its introduction. The veterinary profession is prepared to give its blessing to these Orders. In regard to education the public are very apathetic on the question of pure milk, and this apathy can only be accounted for by their ignorance of the dangers to health that impure milk involves. The educational process must needs, therefore, be slow, and to reach the " man in the street " the propaganda would have to be simple, descriptive, and unusual. If, for example, there were thrown upon the cinema screens specimens of (1) impure milk showing debris, &c., (2) pathogenic germs found in milk, and the diseases they produce, not forgetting to mention the number of children who die annually from bovine tuberculosis, the public would soon realise the risks they were running and a demand for the pure article would follow.

I recognise that such an insight by the layman might do some initial harm to the milk industry, but this would only be temporary, for the public demand would compel the dairy industry to put its house in order, and an increased consumption of milk would follow. Public authority has recently instituted a graded system of milk production, but the number of milk producers who have taken it up are so small that it can scarcely be called a success. We are far behind other countries. What impressed me more than anything at The Hague Dairy Exposition of 1911 was the kindly, elaborate, and thorough manner in which the Government authorities educated the small farmers on the essentials necessary to produce a pure, clean milk.

I am, Sir, yours faithfully,
W. M. SCOTT, F.R.C.V.S.

Bridgwater, Sept. 23rd, 1924.

THE TRANSMISSION OF ENCEPHALITIS LETHARGICA.

To the Editor of THE LANCET.

SIR,—I should be glad if you would give me this opportunity of commenting on a review of encephalitis lethargica which you summarise in THE LANCET of Sept. 27th. In this review Dr. Da Fano repeats certain criticisms made by Dr. S. Flexner and others concerning the transmission of encephalitis lethargica to rabbits. These writers state that they doubt whether encephalitis lethargica has ever been transmitted to rabbits at all. A criticism based on the fact that a spontaneous encephalitis is known to occur in rabbits, and on the difficulty of obtaining positive inoculation results at the present moment. In the period between 1918 and 1921 I consider that I successfully raised the virus from human material on several occasions and carried the virus on in series in rabbits. Previous to these results many failures were obtained, chiefly on the fact that monkeys were used instead of rabbits. Similar positive results were obtained by Loewe, Hirshfield and Strauss, Levaditi and Harvier, and others.

In reply to these criticisms might I point out that they can only have been made by writers who had not weighed carefully the evidence of the literature before them, and who were unfamiliar with the histological lesions of true experimental encephalitis ? In support of this contention the following facts can be urged. It was only from human material showing the definite lesion of encephalitis lethargica that an experimental encephalitis was produced on inoculation. Control inoculations consisting chiefly of material believed to come from cases of encephalitis which subsequently on histological examination proved not to be cases, did not produce an encephalitis.

The spontaneous encephalitis of rabbits is uncommon amongst our laboratory rabbits, as no case has been found in a very large number of examinations, and similar results have been obtained in the last year when many cerebral inoculations have been made during the course of another research. The histological lesion in the spontaneous encephalitis of rabbits is really of the nature of a granuloma with numerous large epithelioid cells, while that of experimental encephalitis lethargica is a perivascular sheath infiltration of small round cells (chiefly lymphocytes) with focal accumulations of similar cells in the brain substance.

There should, therefore, be no difficulty in distinguishing these two, even to the inexperienced, and the possibility of staining the parasite of the rabbit encephalitis gives a further conclusive control.

I am, Sir, yours faithfully,
JAMES MCINTOSH.

The Bland-Sutton Institute of Pathology,
Middlesex Hospital, London, W. 1,
Sept. 30th, 1924.

Obituary.

WALTER HAMILTON ACLAND JACOBSON, M.CH. OXF., F.R.C.S. ENG.

THE recent death of Mr. W. H. A. Jacobson at his residence in Kent, where he had lived in retirement for over 15 years, will recall to many old students of Guy's Hospital a great teacher of surgery, whose arresting personality, brilliant intellect, and amazing powers of expression made everything he said and wrote interesting and memorable. Jacobson was educated at Oxford and Guy's Hospital. He took his B.A. (first class in Natural Sciences) in 1869, and became M.R.C.S. Eng. in 1872, gaining his Fellowship three years later. As assistant surgeon at Guy's Hospital he was appointed teacher of operative surgery in the medical school, later becoming lecturer on anatomy. He was also surgeon at the Royal Waterloo Hospital for Children and Women.

Jacobson's most enduring and laborious work was the compilation of "The Operations of Surgery," first published in 1889, which has since run through six editions, of which the last appeared in 1915. The first edition, in one volume, was a bold attempt on the part of the author to treat the subject of operative surgery in a much more complete and detailed manner than had been done by any of the contemporary English or American authors, and succeeded in becoming the best general treatise on surgical operations in the English language. Subsequent editors, in order to bring it up to date, have had to delete much of the original matter, but no one who has the first edition parts with it. The descriptions of the operations were clear, accurate, and detailed, and the work was far more than a mere guide to operating on the cadaver. The success of this book exceeded all expectations, for its wealth of clinical experience and its accurate description of operations made it indispensable to every surgeon; not a few still speak of it as their Bible. In 1893 Jacobson published the results of some ten years' work in "The Diseases of the Male Generative Organs." Before that date many valuable articles and monographs on this branch of surgery had appeared in France, Germany, and England, and Jacobson, just when some correlation in this field was needed, gathered up the results obtained and formulated the position of contemporary knowledge. From 1893 to 1898 he examined for the Royal College of Surgeons of England as a member of the Board of Examiners in Anatomy and Physiology, and as a member of the Court of Examiners from 1900 to 1905.

Jacobson was possessed of literary ability far beyond the common. His In Memoriam notice of John Hilton, which appeared in Guy's Hospital Reports, of which Jacobson was for many years joint editor, is a model in style. His articles in the "System of Surgery," edited by Homes and Hulke, on fractures, injuries of the back, injuries of the face, and others, were generally recognised as among the best in that work. He did not write many papers, but the few were good. Among them might be mentioned his articles on diseases of the foot and ankle and on diseases of the scrotum in Heath's "Dictionary of Surgery." Of his medical writings in Guy's Hospital Reports, his account of Five Cases of Chancre in Medical Men may be mentioned as an example of lucid description. In THE LANCET his name appeared frequently as a speaker on such subjects as lumbar nephrolithotomy, the surgical sequelæ of fevers, and vesical calculi, in the Clinical Society of London, and of the Harveian Society, of both of which he was an enthusiastic member, and in 1883 he published a series of remarks on the entire removal of the tongue with scissors by the Whitehead method.

Of his qualities as a teacher and as a man Sir William Hale-White sends the following appreciation: "All my surgical appointments were either under Jacobson or Sir Henry Howse, whose assistant surgeon Jacobson was. He was the best teacher I have ever met, partly from a great natural gift, partly from the trouble he took. The theatre was always packed, those who were not there in time could not find a seat. Crowds attended his out-patients, his demonstrations, and his visits to the wards. Hilton in his last years said, 'I know I used to be down upon the men, but I did it for their good.' The same was true of Jacobson. His straight speech to the idler would have been resented had it come from anyone else, but all forgave on account of their knowledge that his object was to make them learn. No one will ever know a tithe of all that he did for the students when they were in trouble, they loved him, and recollected him long after they had left the hospital. He was a man who always remembered little things. I was sitting with him in his study one evening when Sir Henry Howse's servant brought Jacobson a brace of pheasants. He went into the hall, thanked the man, gave him some cigars for his trouble, came back, and in two minutes jumped up saying that as Howse did not smoke and disliked the smell, he ought not to have given his servant cigars. Thereupon he rushed down the street, recovered the cigars, and gave the man money instead. His honesty, his true kindness, his genius for teaching both orally and by writing, and his personality gave him a great position, and have created a lasting affectionate remembrance of him among the hundreds of students who came under his influence."

Somewhat late in life Jacobson was very happily married, but the tragic drowning of his little son and only child cast a shadow over his later years. He then gave up his appointment at Guy's Hospital and his private consulting practice, and retired to his country house at Hawkhurst. He loved the country and country folk and tramped about during many a long day. He was devoted to his wife, to his garden, and to his poor neighbours, especially the children. Needless to say they returned his love and brought him occupation and happiness.

HENRY GERVIS, M.D., F.R.C.P. LOND.

Dr. Henry Gervis, consulting obstetrician to St. Thomas's Hospital, whose death occurred on Sept. 25th at his house in Bath, had reached the advanced age of 86. Throughout a long professional career he was well known as a great obstetrician.

Born in 1837 at Tiverton, he was educated at Mill Hill School and Trinity College, Cambridge, entering the medical profession through St. Thomas's Hospital Medical School. A successful student, he obtained both exhibitions and gold medals at the University of London; he graduated M.D. in 1861 and took the M.R.C.P. Lond. in the following year, 12 years later being elected F.R.C.P. At St. Thomas's Hospital he filled in succession all the obstetrical posts, becoming consulting obstetric physician on his retirement. Over his long period of active service he was not only a valuable member of the staff but a distinguished teacher.

One of his pupils, now himself of consulting rank, writes as follows: "Those who had the privilege of working under Gervis during their curriculum at St. Thomas's Hospital remember with gratitude the instruction which he gave them in his special branch of work. Always considerate towards his patients, he inculcated into his clerks and house officers the necessity of kind and gentle treatment of every patient, no matter how troublesome she might be in her elaboration and repetition of symptoms. He was physician to the hospital at a time when the obstetric physician was regarded as a prescriber of medical remedies rather than as a surgeon. The surgeons permitted him to perform operations, but not those which involved opening of the peritoneum. As this branch of the obstetric art was practically non-existent in the days when Gervis first joined the staff, there was no complaint, because it was the custom at all hospitals to restrict the operations of the gynæcological department to those which could be performed per vaginam. When doing these he was careful, cleanly in his work, and very thorough, taking the opportunity of demonstrating the advantages of the method which had been employed as compared with others. It is not surprising that he gained a great influence over his patients and he was spoken of with affection by them long after he had retired from the active practice of his profession. As a lecturer he was clear in diction and always succeeded in making his lectures interesting. One knew that they contained not only the recent ideas on the subject, but also conveyed his own matured judgment. He was pleased to discuss any apparently obscure point, and never conveyed the impression that it was a trouble to do so, although the large extent of his practice as a consultant must often have rendered any such discussion more than inconvenient. To one who was a clinical clerk and afterwards resident accoucheur in his clinique, the memory of Henry Gervis will always be an abiding and a happy one. Of tall figure, graceful carriage, and pleasant manner, the friendly expression of his face as he turned to answer some question, adjusting his spectacles as he did so with thumb and little finger, is still distinct, though many years have passed since the last impression was received."

To this sympathetic but accurate document little addition is necessary to show Dr. Henry Gervis's claims to be regarded as a professional leader. His fairness and accuracy assured his selection as an examiner and he discharged this office for the Universities of Cambridge and London and the Royal College of Physicians of London. He was elected President of the Obstetrical Society and of the Hunterian Society, before the latter of which he delivered the Annual Oration as long ago as 1875. He was not a prolific author, but whatever he wrote was informed by his personal experience, and valuable papers will be found by him in the St. Thomas's Hospital Reports on such subjects as hydramnios, the anatomy of the hymen, and puerperal septicæmia. He also wrote the article on sterility in Allbutt and Rolleston's System, and contributed the article on phlegmasia dolens to Quain's Dictionary of Medicine. In private life Dr. Gervis was a keen archæologist, being a Fellow of the Society of Antiquaries and of several archæological associations. His only son is a member of the medical profession.

HARTLEY LUPTON.

BY the death of Mr. Hartley Lupton physiology has lost one of the best and keenest of its recent recruits. Lupton was originally trained as a physicist, and his first work was carried out at the University of Manchester, of which he was a student, on radium. He then proceeded to study for a medical degree, but found that research work in physiology offered greater attractions. Under the guidance of Prof. A. V. Hill he commenced an investigation into the physiology of muscular contraction and muscular work in the human subject, and as a result of three years of very hard work, continued up to the time of his death, he contributed very materially to our knowledge of this branch of human physiology. His work served to illustrate in a surprisingly clear manner the application of academic knowledge to facts of everyday life. He faced death, as he lived, with constant fortitude, and his open and generous character will be missed by a large circle of friends in Manchester and in London, where his life's work came to its abrupt end.

Medical News.

UNIVERSITY OF LONDON.—A course of three lectures on La douleur, au point de vue des fonctions affectives et perceptives will be given in French by Prof. Henri Piéron, of the Sorbonne, Paris, in October. Further details will be announced later. The Semon lecture, entitled Malignant Disease of the Gullet, will be given in French by Dr. D. Guisez, of Paris, at the rooms of the Royal Society of Medicine, 1, Wimpole-street, W. 1, on Thursday, Nov. 6th, at 5 P.M. Admission to these lectures is free. A course of 24 University extension lectures on the History of Science will be given by Dr. Charles Singer at Gresham College, Basinghall-street, London, E.C. 2, on Mondays, at 6 P.M.

University College.—To-day (Friday), at 5.30 P.M., Prof. T. Percy Nunn will lecture on the Scientific Interpretation of Nature. This lecture is introductory to the new course for the M.Sc. on the Principles, History, and Method of Science. Prof. E. H. Starling will be in the chair. The lecture is open to the public without fee or ticket. A public lecture will be given on Oct. 8th, at 6 P.M., by Prof. C. Spearman, F.R.S., on the Current Views of Individual Differences in Ability.

The following elections have been made in the Faculty of Medical Sciences at University College, London: To the Bucknill Scholarship, of the value of 160 guineas, Mr. D. F. Ogborn (Wood Green County School). To Exhibitions of 55 guineas each: Mr. W. A. Wilson (Hornsey County School) and Mr. H. Tomkin (Coopers' Company School). To the Epsom Medical Scholarship, Mr. R. W. Haines. To an additional Scholarship, Mr. P. A. Cooper, also of Epsom College.

King's College.—A special course of eight lectures on the Histology of the Nervous System will be given during the Michaelmas Term (October–November), in the Physiology Lecture Theatre of the College, Strand, W.C. 2, by Dr. C. Da Fano, reader in histology in the University. The lectures will be accompanied by demonstrations of specimens, and will be held on Wednesdays at 4.30 P.M., beginning on Oct. 8th. The course is free to all students of London colleges, and to medical men and others on presentation of their visiting cards. The course has been recognised by the University of London as one of the special courses for the B.Sc. honours degree.

Five lectures on the Human Body and its Function will be given by Prof. R. J. S. McDowall on Wednesdays, at 5.30 P.M., beginning on Oct. 8th; four lectures will be delivered by Dr. E. W. Scripture, at 5.30 P.M., on Oct. 6th, 13th, and 20th, and Nov. 3rd. Six intercollegiate lectures, open to the public, on Scientific Method, will be given on Fridays, at 5.30 P.M., beginning on Nov. 7th by Prof. E. W. Hobson, F.R.S., Prof. L. T. Hobhouse, Prof. E. G. Coker, F.R.S., Prof. E. W. MacBride, F.R.S., Dr. E. S. Russell, and Prof. A. V. Hill, F.R.S.

Parliamentary By-election.—At a meeting of the London University supporters of the Labour Party on Sept. 25th, F. G. Bushnell, M.D., B.S. Lond., D.P.H. Camb., was unanimously adopted as Labour candidate in the coming by-election. Dr. Bushnell graduated in medicine from University College Medical School in 1891, and during the war served in the R.A.M.C. (27th Division) in France and Macedonia. He is now tuberculosis medical officer, deputy medical officer of health, and joint bacteriologist to the Plymouth Borough Council. His active association with the Labour Party dates back some years, and his report on the employment and after-care of tuberculous persons which appeared in THE LANCET of Sept. 27th was drawn up at the request of the advisory committee of the Trades Union Congress and Labour Party.

LONDON MEDICAL EXHIBITION.—This exhibition which has now become a feature of the medical year, will open at the Central Hall, Westminster, London, S.W., on Monday, Oct. 6th, and close on Friday, Oct. 10th. Established in 1905 its scope has now been enlarged in an attempt to cover the whole range of agencies for medical treatment. The exhibition, which is open to medical men only, will comprise the most recent organo-therapeutic, bacteriological, and pharmaceutical remedies and prophylactics; electro-therapeutic apparatus; scientific dietary; surgical instruments; hospital furniture and medical appliances, diagnostic material, and apparatus; pathological and physiological apparatus; artificial limbs, aids in invalidity and deformity; sick-room requisites; natural and artificial hydrotherapy; professional literature; hygienic clothing, and so forth. Invitation cards can be obtained from the secretary of the exhibition, 194–200, Bishopsgate, London, E.C., or at the Central Hall during the exhibition.

TAVISTOCK CLINIC.—A course of ten lectures on Elementary Psychotherapy will be given at the Tavistock Clinic for Functional Nerve Cases, 51, Tavistock-square, W.C., by Dr. H. Crichton Miller on Mondays, at 5.30 P.M., beginning Oct. 13th. A syllabus of the lectures and further details may be obtained from the lecture secretary at the clinic.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—A course of lectures for medical practitioners will be delivered at the hospital on Thursdays at 4 P.M., from October to December. The course will open on Oct. 9th, when Mr. F. G. Doyne will deal with Dacryocystitis Neonatorum. The other lectures will be announced appropriately in our Medical Diary. The lectures are free to medical practitioners.

NATIONAL INSTITUTE FOR THE BLIND.—The After-care Department of the National Institute for the Blind states that during August 45 new cases came under their care (19 men and 26 women). Gifts, inclusive of clothing, to the number of 21 were provided at a cost of £37. The amount expended in training fees was £49, in relief £360, and in relief administered by branehes £143.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The annual dinner of this society will be held at the Hotel Cecil, Strand, W.C., on Friday, Oct. 17th, at 7.30 P.M. The Minister of Health hopes to attend, and others who have accepted include the Bishop of Winchester, Sir Alfred Mond, Major Haden Guest, M.P., Sir Humphry Rolleston, P.R.C.P., Sir Arthur Robinson, Sir George Newman, and Major-General J. E. B. Seely. A musical programme is being arranged to follow the dinner. Ladies are invited, and members are asked to give early notice to the executive secretary, 1, Upper Montague-street, Russell-square, W.C. 1, of their intention to be present, with the names of their guests. A payment of 12*s.* 6*d.* for each ticket should be included with applications sent before Oct. 11th; after that date the cost of tickets will be 15*s.* each.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—A special post-graduate course will be held this week end, Oct. 4th, 5th, and 6th. On Saturday, Oct. 4th, at 11 A.M., Mr. T. G. Stevens will lecture on Chronic Metritis and Allied Disorders, and at noon Sir William Willcox will discuss the Toxic Factor in Disease. At 2 P.M. Dr. C. M. Wilson will speak on Neurology: the Essential Minimum, to be followed at 3 P.M. by Dr. A. Hope Gosse on Common Cardiac Irregularities. On Sunday, Oct. 5th, there will be two lectures, one at 10.30 A.M., on Diet and Disease, by Prof. B. J. Collingwood, and one at 11.30 A.M., on Surgical Treatment of Gastric Ulcer, by Prof. C. A. Pannett. Mr. Zachary Cope will address the first meeting on Monday, Oct. 6th, at 10 A.M., taking for his subject Differential Diagnosis of Acute Right Hypochondriac Pain; Mr. Aleck Bourne will speak at 11 A.M. on the Investigation of a Case of Puerperal Fever, and Mr. Gordon Bryan will discuss the Diagnosis of Acute Abdominal Illness in Children at noon. Dr. Reginald Miller will lecture on Colonic Toxæmia and its Medical Treatment at 2 P.M., and the concluding lecture will be delivered at 3 P.M. by Dr. J. B. McDougall on Some Practical Points in the Diagnosis and Treatment of Pulmonary Tuberculosis. The course is open to all medical practitioners without fee, and will be held in the Library of St. Mary's Hospital Medical School (South Wharf-road entrance or Cambridge-place entrance).

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Monday, Oct. 6th, will begin a series of post-graduate lectures on cancer, delivered in the West Lecture Hall of the Royal Society of Medicine, Wimpole-street, at 5.30 P.M. The first lecture, on the General Pathology of Cancer, will be given by Dr. Archibald Leitch. The second lecture takes place on Wednesday, the 8th, when Sir Thomas Horder will lecture on Cancer from a Medical Point of View. These lectures are open to all members of the profession, and no fees are charged. The second week of the course in psychological medicine at the Bethlem Royal Hospital begins on Tuesday, the 7th. This course is a series of lecture-demonstrations given on Tuesdays and Saturdays, at 11 A.M., by Dr. Porter Phillips and Dr. Thomas Beaton. On Tuesday also begins the series of eight clinical demonstrations on tropical medicine, to be given at the London School of Hygiene and Tropical Medicine, by Dr. G. C. Low and Dr. P. H. Manson-Bahr, at 2 P.M.; the second demonstration takes place on Thursday at the same time. On Wednesday, Oct. 8th, at 5.30 P.M., will be given the first of four lecture-demonstrations on Treatment by Electrotherapy at the Royal Free Hospital, by Dr. C. B. Heald. Full particulars and syllabuses of all these courses may be obtained from the Secretary of the Fellowship of Medicine, 1, Wimpole-street, W. 1.

CITY OF LONDON HOSPITAL FOR DISEASES OF HEART AND LUNGS.—A short intensive course for post-graduates will be held at the hospital at Victoria Park, E., from Monday, Oct. 13th, to Friday, the 17th. On the first day, Oct. 13th. Dr. J. Browning Alexander will lecture on Diabetes and Tuberculosis at 11 A.M., and Dr. S. R. Gloyne will lecture on the Pathology of Pneumothorax at 2.30 P.M. Subsequent lectures will be announced in the Medical Diary, and further particulars may be had from the Dean of the hospital.

MEDICAL SOCIETY OF LONDON.—The syllabus of the first half of the session has just been issued. On Oct. 13th. at 8 P.M., the annual general meeting will be held, to be followed, at 8.30 P.M., by the President's address on Medical Memories, by Dr. E. M. Callender. On Oct. 27th, at 8.30 P.M., there will be a clinical evening, with exhibition of cases and skiagrams. On Nov. 10th, at 8.30 P.M., a discussion on Encephalitis Lethargica will be introduced by Dr. E. Farquhar Buzzard, followed by Prof. A. J. Hall, Prof. J. McIntosh, Dr. A. Salusbury MacNalty, and others. On Nov. 19th, at 5 P.M., the Lloyd Roberts lecture on the Renaissance of Midwifery will be delivered by Dr. Herbert Spencer. The meeting on Nov. 24th, at 8.30 P.M., will be devoted to a discussion on the Treatment of Senile Gangrene, to be introduced by Sir Anthony Bowlby, followed by Dr. H. des Vœux, Mr. Sampson Handley, and others. On Dec. 8th, at 8.30 P.M., a discussion on the Present Position of the Treatment of Diabetes by Insulin will be introduced by Dr. George Graham, followed by Prof. H. MacLean and others. The Lettsomian lectures on Wounds and other Injuries will be delivered in February and March, 1925, by Sir Bernard Spilsbury. The annual oration on the Medical Career of John Keats will be delivered in May, 1925, by Sir William Hale-White.

MEDICAL DEFENCE UNION.—The annual general meeting of this Union was held at the Brighton, Hove, and Preston Dispensary on Thursday, Sept. 25th. The President, Mr. Walter G. Spencer, F.R.C.S., was in the chair, and 26 other members were present. In moving the adoption of the annual report of the Council for the year 1923–24, the President congratulated the members upon the satisfactory position now occupied by the Union. The first year in the new offices had been attended by a marked increase in the number of applicants for membership. Already the number of new members elected in the nine months of the current year (over 1200) exceeded that of the whole of any previous year, the roll of members now having reached a total of over 11,800. The President referred in feeling terms to the death of Sir John Tweedy, a former president, and Dr. J. Roche Lynch and Dr. A. C. Roper, former members of the Council, and also to the loss which the Union had sustained through the retirement of Dr. M. Hallwright from the Council owing to ill-health. He congratulated the Union on the efficient services rendered to the Union by the general secretary and his clerical staff. The very full and clear report supplied by the solicitor was highly satisfactory, and there had been remarkable success in those legal actions which the solicitor had advised the Union to undertake during the past year. The annual report of the Council and the financial statement for the year 1923 were adopted unanimously. Sir Charles Ballance, Dr. E. C. Greenwood, and Dr. W. S. A. Griffith were unanimously re-elected members of the Council. The auditors were reappointed for the current year and a hearty vote of thanks was accorded to the President and Council for their services during the past 12 months. At the conclusion of the annual general meeting an extraordinary general meeting was held, when proposals submitted by the Council for alteration of the Articles of Association were unanimously adopted.

BRIGHTON WATER-SUPPLY.—Despite the troubles in the building trade building developments are going on on a large scale in Brighton and in the surrounding district, which includes Rottingdean in an eastward direction and Shoreham-by-Sea in the westward. Large houses and small ones which formerly sheltered but one family are being converted into flats, thus adding to the population by leaps and bounds. The demands upon the water-supply have been increasing very rapidly, and careful watchings have shown that while the limit of the supply has by no means been reached, the limit of the pumping capacity and also the limit of the storage capacity have been reached. These facts were brought to the notice of the corporation, and that body by a unanimous vote on Sept. 25th decided to proceed forthwith with an estimated expenditure of £106,855 by way of extensions of the pumping stations and reservoirs and other concomitant works. The waterworks undertaking at Brighton has unexhausted borrowing powers sufficient to cover this large figure, and this will save the necessity of any application being made to Parliament.

SUMMER Time in France will cease at midnight on Saturday, Oct. 4th, when the clocks will be put back one hour. This is practically a fortnight later than in England.

A SUM of £35,287 has been distributed to various London hospitals and charities out of the collections made on Alexandra Day, June 25th, which amounted to £40,423.

MEMORIAL TO THE LATE DR. J. EVAN JONES.—A memorial in the form of a lych gate at the entrance to Ludgershall churchyard, Wiltshire, erected by former patients and friends, was recently dedicated to the memory of "James Evan Jones, M.R.C.S., L.R.C.P., born April 18th, 1869, died April 15th, 1923." Dr. Jones, who was educated at Llandovery College and St. Bartholomew's Hospital, had practised medicine in the district for over 20 years.

UNIVERSITY OF MELBOURNE: CHAIR OF DENTAL SCIENCE.—To this newly created chair Mr. F. C. Wilkinson, B.D.S., M.D., of the University of Liverpool, has been appointed. Prof. Wilkinson commenced his dental studies in 1906 under Prof. W. H. Gilmour, and in 1912 took the degree of B.D.S. with honours, graduated as M.B. and Ch.B. in the same year, and in 1917 obtained the degree of M.D. From 1915–18 Dr. Wilkinson served with the R.A.M.C. at the Liverpool Merchants' Mobile Hospital in France. Since then he has been engaged in private practice and has also held various appointments at the University and at the Dental Hospital.

UNIVERSITY OF LIVERPOOL: CLINICAL SCHOOL.—The hospitals comprising the Liverpool Clinical School are again arranging to hold lecture-demonstrations for practitioners during the University terms. The programme is so planned that on any one day a demonstration is given by one hospital only. All demonstrations will commence at 3.30 P.M. The lecture-demonstrations will be largely clinical in character; the lecturers and subjects will be arranged by individual hospitals and will include in rotation all the various clinics covered by the hospital concerned. The programme for the week commencing Oct. 6th will be found in the Medical Diary, p. 733. Further particulars may be obtained from the Secretary, 61, Rodney-street, Liverpool.

LIVERPOOL PSYCHOLOGICAL SOCIETY.—The second session of this society will commence on Oct. 7th, when Dr. Betts Taplin, the President, will deliver an inaugural address on the Power of Suggestion at the University of Liverpool at 8 P.M. The society's first session has been very successful, and an interesting programme of scientific research has been arranged for the coming winter. Further particulars may be obtained from the secretary, The University, Liverpool.

WIRELESS CONCERTS FOR LIVERPOOL PATIENTS.—A six-valve wireless receiving set has just been installed in the City Sanatorium at Fazakerley, Liverpool, and has been connected up by overhead wiring to seven wards in which loud speakers have been placed. In helping to relieve the monotony of prolonged sanatorium routine, wireless, it is felt, will be of the utmost value. The stimulus came from an enthusiastic patient, who put together a small set of his own, together with an ear-piece, which he hung by his bed.

DONATIONS AND BEQUESTS.—Under the will of the late Miss Mary Wilson Mitchell, of Macrocarpa, Ventnor, the testatrix left among other bequests £8000, as the trustees of her will may think fit, for distribution among war or other charities, institutions, hospitals, convalescent and nursing homes; £1000 each for a Mitchell bed in the Women's Block of the Royal National Hospital for Consumption, the Church Missionary Society, and the Church of England Zenana Missionary Society; £500 each to the London Hospital, Guy's Hospital, St. Bartholomew's Hospital (New Hospital Building Fund), St. Thomas's Hospital, the Middlesex Hospital (for the Cancer Research Laboratory), the Royal Northern Hospital, the Hospital for Epilepsy and Paralysis, Maida Vale, the Mildmay Mission Hospital, the Royal Isle of Wight County Hospital (for a Mitchell bed in the women's ward), Lord Mayor Treloar's Cripples Home and College (for a Mitchell cot), and King Edward's Hospital Fund for London; and £300 each to the Poplar Hospital, the Royal Free Hospital, and the Cancer Hospital, Fulham.—Among bequests left by the late Mr. Jabez Gurteen, J.P., of Haverhill, Suffolk, and of Sturmer, Essex, is one of £1500 to the Royal Surrey County Hospital, Guildford.—By the will of the late Sir Walter James Buchanan, K.C.I.E., sometime editor of the *Indian Medical Gazette*, he left, in addition to property in Ireland, personal estate in England of the net value of £9348. He bequeathed one-thirtieth of all his other property, after a bequest of £7000, to Sir Patrick Dun's Hospital, Dublin.

MANCHESTER MEDICAL SOCIETY.—This society, of which Prof. G. R. Murray is President, will hold its opening meeting for the session on Wednesday, Oct. 8th, at 8 P.M., when Dr. Arthur F. Hurst will deliver a lecture on the Sphincters of the Alimentary Canal and their Clinical Importance. A full syllabus of the meetings may be obtained from the hon. secretary, Dr. A. Hillyard Holmes, The University, Manchester.

MANCHESTER JEWISH HOSPITAL EXTENSION.—Lord Leverhulme recently laid the foundation-stone of the new nurses' home which is being added to the Victoria Memorial Jewish Hospital. The building will cost at least £15,000, which does not include equipment. To this end an appeal has been launched for half a million shillings. Although founded and managed by Jews, the hospital is open to all people irrespective of race or creed. At present there are 38 beds and a staff of 14 nurses. The new building will raise the number of beds to 52, and the nursing staff will be increased to 28, and the hospital will then be able to qualify as a training centre for the certificate of the General Medical Council. Already 25,000 shillings have been collected or promised. Last year the hospital treated 9800 in-patients and out-patients at a cost of 11*s.* 6½*d.* per patient.

BRADFORD MENTAL DEFECTIVES.—At a meeting of the Mental Deficiency Committee of the Bradford Corporation held last week, it was resolved to submit a scheme for a new mental institution to the City Council and the Ministry of Health. The new institution would accommodate 340 patients, and would cost £133,000; later it is hoped to extend the scheme to provide for 500 patients. The additional total expenditure involved is anticipated to be £6240 per annum, half of which sum will be met by the Board of Control. The scheme comprises the erection of administrative buildings, a laundry, a recreation hall, a hospital, and accommodation for doctors and nurses. One of the benefits of the institution will be that it will be possible to separate patients of varying stages of intelligence in different buildings and grades.

LADIES' MEDICAL GOLFING SOCIETY.—The autumn meeting was held at Addington on Sept. 26th. The scratch prize was won by Mrs. Collis-Browne with a score of 89, after a tie with Mrs. de Paula. The senior handicap prize was won by Mrs. Lucas Keene, M.B. (95 – 19=76), and the junior handicap prize by Mrs. H. Carson (112 – 26=86). The special prize for the aggregate of spring and autumn meeting scores under handicap was won by Mrs. Collis-Browne (83 net + 85 net=168), who also won the fourball foursomes competition in the afternoon, partnered by Mrs. Lucas Keene. The meeting was to some extent marred by bad weather, but thanks to the untiring energy of Miss Cecil Leitch, the captain, who acting as hon. secretary made herself responsible for all arrangements, it was nevertheless a most successful one.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Oct. 7th.

ORTHOPÆDICS: at 5.30 P.M. (Cases at 5 P.M.)
Presidential Address:
Mr. H. A. T. Fairbank: Some Affections of the Epiphyses.
Cases illustrating Unusual Conditions of Epiphyses will be shown.

Thursday, Oct. 9th.

NEUROLOGY: at 8.30 P.M.
Presidential Address:
Dr. E. Farquhar Buzzard: The Evolution of Neurology and its Bearing on Medical Education.

Friday, Oct. 10th.

CLINICAL: at 5.30 P.M. (Cases at 5 P.M.)
Cases:
Sir StClair Thomson: Two Cases of Persistent Paralysis of One Vocal Cord from a Tubercular Lesion involving the Recurrent Laryngeal Nerve.
Dr. F. Parkes Weber: Recklinghausen's Disease with Left Lateral (suprazygomatic) Meningocele, simulating a Soft Fibromatous Fold of Skin.
Other cases will be shown.

OPHTHALMOLOGY: at 8.30 P.M. (Cases at 8 P.M.)
Cases will be shown.
Presidential Address:
Sir Arnold Lawson: Tinted Lenses and their Uses.
Discussion is invited.
Paper:
Mr. A. F. MacCallan: Cataract Operations in Egypt.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

Monday, Oct. 6th, to Saturday, Oct. 11th.—West Lecture Hall, Royal Society of Medicine, W. Lectures arranged by the Fellowship of Medicine and open to all members of the medical profession. To start at 5.30 P.M. Mon., Dr. Archibald Leitch: The General Pathology of Cancer. Wed., Sir Thomas Horder, Bt.: Cancer from a Medical Point of View.—Bethlem Royal Hospital. Lecture-Demonstration on Tues. and Sat. at 11 A.M., by Dr. Porter Phillips and Dr. Thomas Beaton.—London School of Hygiene and Tropical Medicine. Tues. and Thurs., 2 P.M., Dr. G. C. Low and Dr. Manson-Bahr: Clinical Demonstrations on Tropical Medicine.—Royal Free Hospital, Wed., 5.30 P.M., Dr. C. B. Heald: Lecture-Demonstration on Treatment by Electro-Therapy, illustrated by cases under treatment at the hospital.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, Oct. 6th.—11 A.M., Surgical Registrar: Surgical Wards. 12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards.

Tuesday.—11 A.M., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

Wednesday.—12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Dr. Owen: Medical Out-patients. Dr. Pernet: Skin Dept.

Thursday.—12 noon, Medical Registrar: Clinical Methods. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

Friday.—11 A.M., Dr. McDougal: Medical Electricity. 12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

Saturday.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M., to 6 P.M., Saturdays, 10 A.M., to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, Oct. 9th.—4 P.M., Mr. Doyne: Dacryocystitis Neonatorum.

ST. JOHN'S HOSPITAL, Leicester-square, W.C.

Tuesday, Oct. 7th.—5 P.M., Dr. J. H. Stowers: Chesterfield Lecture.

Thursday.—5 P.M., Dr. J. M. H. MacLeod: Anatomy.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)

Monday, Oct. 6th.—(At the Children's Hospital.) Mr. W. A. Thompson: Hare-Lip and Cleft Palate.

Tuesday.—(At the Southern Hospital.) Mr. Douglas-Crawford: Surgical Cases.

Wednesday.—(At the Northern Hospital.) Mr. Rawlinson: Prostatism.

Thursday.—(At the Stanley Hospital.) Dr. Gullan; Action of Thyroid and Pituitary Glands.

Friday.—(At the Royal Infirmary.) Dr. Bigland: Medical Cases, particularly Neurological.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

Tuesday, Oct. 7th.—4.15 P.M., Sir John Bland-Sutton: Attic Salt for Gall-stones (Lloyd Roberts Lecture).

Friday.—4.15 P.M., Prof. H. S. Raper: Fat Metabolism and Some of its Disorders.

Appointments.

Collins, F. G., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health for the Borough of West Ham.

Kettle, Edgar Hartley, M.D., B.S., Professor of Pathology and Bacteriology to the Welsh National School of Medicine, to be Honorary Pathologist and Bacteriologist to the Cardiff Royal Infirmary.

Lester-Williams, R., M.B., B.Ch. Camb., F.R.C.S. Eng., Resident Surgical Officer, Sheffield Royal Infirmary.

Gloucestershire Royal Infirmary: Terry, H. C., M.B., Ch.B. Birm., Physician, and Davey E. N., M.B., B.Ch. N.U.I., Assistant Physician and Pathologist.

St. Mary's Hospitals, Manchester: Foulds, E. J., M.B., Ch.B. Manch., and Latham, T., L.R.C.P. Lond., M.R.C.S., House Surgeons.

Surgeons under the Factory and Workshop Acts: Rogers, H., M.B., B.Ch. Dub. (Milborne Port, Somerset); Evans, G. O. D., L.R.C.P. & S. Edin. (Festiniog, Merioneth).

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne, District Infirmary.—H.S. for six months. £75.

Birmingham City Education Committee.—Asst. Sch. M.O. £600.

Blackburn Union and Infirmary.—Res. Asst. M.O. £200.

Bristol Royal Hospital for Sick Children and Women.—H.P. £125.

Bristol Royal Infirmary.—Hon. Dermatologist and Hon. Asst. S. to Ear, Nose, and Throat Dept.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Second Res. H.S. £75.

Dumfries, Crichton Royal Mental Hospital.—Asst. P. £350.

Durham, Richard Murray Hospital, Blackhill.—Res. M.O. £400.

Gloucestershire Mental Hospitals, Coney-hill, Barnwood.—Jun. Asst. M.O. £350.

Gloucestershire Royal Infirmary and Eye Institution, Gloucester.—Asst. H.S. £150.

Holborn and Finsbury Hospital, Archway-road, N.—Second Asst. M.O. £300.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. £50.

Hospital for Sick Children, Great Ormond-street, W.C.—H.P. and Asst. Cas. O. for six months. Each £50.

Johannesburg, S. African Institute for Medical Research.—Bacteriologist.

Lancaster County Mental Hospital.—Asst. M.O. £582.

Leamington Spa, Warneford, Leamington and South Warwickshire General Hospital.—Res. H.S. £150.

Leicester Royal Infirmary.—H.P. for six months. £62 10*s.*

London Hospital Dental School, E.—Hon. Anæsthetist.

London Temperance Hospital, Hampstead-road, N.W.—Res. M.O. £175. Also Med. Reg. 40 guineas.

Manchester Royal Infirmary.—Res. M.O. £200. Also Asst. M.O. £100.

Miller General Hospital for South-East London, Greenwich-road, S.E.—H.P. £125.

Napsbury Mental Hospital, near St. Albans, Herts.—Fourth Asst. M.O. £526 10*s.*

Paddington Green Children's Hospital, W.—H.S. for six months. £75.

Royal Chest Hospital, City-road, E.C.—P.

Royal Free Hospital, Gray's Inn-road, W.C.—Med. Reg. £250.

Royal Naval Medical Service.—Surg. Lieuts. 25*s.* per day.

Royal Northern Hospital, Holloway, N.—H.P. and H.S. £75.

Salford Union Infirmary, Hope, Pendleton, near Manchester.—First Asst. Res. M.O. £300.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Cas. O. and R. £150.

Westminster Hospital.—Obstetric S. and Asst. Obstet. S.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Castleton, Derbyshire; Wellingborough, Northamptonshire; Swaffham, Norfolk.

The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for the districts of the Blackpool (Circuit No. 4). Applications should reach the Private Secretary, Home Office, not later than Oct. 18th.

Births, Marriages, and Deaths.

BIRTHS.

Lempriere.—On Sept. 23rd, the wife of Dr. L. R. Lempriere, of Haileybury College, Hertford, of a daughter.

Sarra.—On Sept. 20th, at "Coverack," Tilehurst-road, Reading, the wife of Dr. Edwin R. Sarra, of a son.

Wilson.—On Sept. 22nd, at Harley-street, W., the wife of Dr. C. M. Wilson, of a son.

Wilson.—On Sept. 23rd, at Putney-hill, S.W., the wife of Alex Wilson, M.D., of a son (still-born).

MARRIAGES.

Spira—Seckel.—On Sept. 25th, at Hampstead, Dr. Jean Jacques Spira, of 35, Harley-street, W., son of Mr. and Mrs. Leon Spira, of Paris, to Esmée Angela, only daughter of Mr. and Mrs. Louis Seckel, of 120, Haverstock-hill, N.W.

DEATHS.

Atkinson.—On Sept. 29th, at Osgathorpe House, near Loughborough, Edith Frances, the wife of Dr. S. E. Atkinson. Funeral Thursday at Chichester. Memorial service at 3 P.M. at Osgathorpe Parish Church.

Deighton.—On Sept. 29th, at St. Bernards, Cambridge, Frederick Deighton, M.A., M.B., surgeon, aged 70.

Gervis.—On Sept. 25th, at Royal-crescent, Bath, Henry Gervis, M.D., J.P., formerly of Harley-street, London, aged 86 years.

Jacobson.—On Sept. 14th, at Lordine Court, Ewhurst, Sussex, aged 77 years, Walter Hamilton Acland Jacobson, M.Ch. Oxon., Consulting Surgeon of Guy's Hospital, last surviving son of the late Bishop Jacobson, of Chester.

Mathewson.—On Sept. 23rd, at Willingham, Cambridge, James W. Mathewson, M.B., Ch.B.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

A CLEAN MILK COMPETITION IN KENT.

BY ALFRED GREENWOOD, M.D., B.SC. MANCH., D.P.H.,
BARRISTER-AT-LAW, MEDICAL OFFICER OF HEALTH FOR THE COUNTY OF KENT.

DURING the earliest quarter of 1923 the first clean milk competition was held in the county of Kent. This competition originated from an inquiry received, during the summer of 1922, by the agricultural organiser to the Kent Education Committee, from a coast town dairy farmer supplying milk to several girls' schools at Broadstairs and Ramsgate. The headmistresses of these schools had been reading articles in a certain daily paper condemning fresh cows' milk on account of the filth and number of dangerous germs it was alleged to contain and, being alarmed at what they read, they asked the farmer supplying their schools with milk for some guarantee that his milk was reasonably clean. As a preliminary step it was arranged that samples of his milk should be taken by the district sanitary inspector and submitted to the county bacteriological laboratory at Maidstone for examination. This was done, but it was soon evident that other farmers were confronted with a similar difficulty, and that the consumption of fresh milk was being restricted by the fact that many members of the public were afraid of it.

Objects of the Competition.

The Agricultural Education Sub-committee of the Kent Education Committee decided, therefore, to organise a clean milk competition for four purposes :—

(*a*) To show that there might be already available a supply of clean milk in the county, in addition to what is sold as Grade A and certified milk.

(*b*) To assist those dairy farmers in the county already interested in, and anxious to produce, clean milk by examining their milk from time to time by visiting their cowsheds, and as a result of the examinations and visits by advising them as to the manner in which their methods could be improved.

(*c*) By friendly rivalry, to stimulate those dairy farmers who entered this competition, *and especially their milkers*, to learn the essential conditions necessary for the production of clean milk, and to encourage them to pay still closer attention to the conditions under which their milk is produced and handled.

(*d*) To demonstrate to dairy farmers, in general, how reasonably clean milk can be produced in ordinary farm buildings, and under ordinary farm conditions, without excessive increase of cost, so that a larger supply of such milk may be available for the public.

The Kent Milk Recording Society and the Kent Education Committee together organised the competition.

Rules for Competitors.

The Kent and Sussex Farmers, Ltd., gave a challenge cup for award to the winning competitor to be held for one year. A diploma was promised to each competitor reaching a sufficiently high standard, and also a certificate for each regular milker on a diploma farm. All successful competitors had the entry fee of £1 returned to them. Money prizes of £5, £4, £3, £2, and £1 were distributed amongst the workers on the first five diploma farms. The competition extended over three months from February to May, 1923, and was open to any dairy herd, not producing Grade A milk, where there were not less than ten cows in milk during the competition. Competitors were required to take and send for bacteriological examination to Wye Agricultural College, Kent, six samples representative of their bulk milk, and also an authorised representative of the committee made surprise visits in order to sample the milk periodically. Also the inspecting judge paid at least one surprise visit to each competitor's herd at milking time, and awarded marks according to a scale of points directly under the control of the farmer—e.g., the general health of the cows, the suitability and care of the utensils and other equipment used in handling the milk, the general method of handling the milk, &c.

The awards were made on the following scale of points :—

Examination of milk		900
Bacterial content and keeping qualities	800	
Chemical analysis	100	
Inspection on the farm		600
Health of cows	100	
Equipment	100	
Methods	400	
Total possible marks		1500

It may be mentioned here that the five prize winners were awarded total marks respectively of 1258, 1165, 1136, 1106, and 1100.

These rules, as set out above, were submitted to the Ministry of Agriculture, who gave them their approval and undertook to pay two-thirds of the net cost of running the competition.

The intention to hold the competition was made known widely. As a result, 53 entries were received, which is a far larger number of entries than has been received for any clean milk competition held in any county in England previously. All competitors were advised before the competition began to read an article written by Mr. J. Mackintosh in the April, 1922, issue of the *Ministry of Agriculture Journal*, and to obtain a copy of the Ministry of Agriculture's Leaflet No. 151 on Cleanliness in the Dairy. They were also sent a copy of the score-card which would be used by the inspecting judge on his surprise visits, so that they might know what were the important points and how many marks would be awarded for each item. The score-card used was the official one recognised by the Ministry of Health slightly amplified. The marks on the score-card were intended to have a strong educational value, so that a farmer with dirty milk, as indicated by a bacterial count, might be told where the fault probably lay.

Methods of Carrying-out.

The 53 competitors were arranged into three groups, with 13 competitors in each, and one group of 14 competitors. Each competitor had to submit one sample of morning milk every fortnight. Two sterilised glass (8 oz.) bottles were sent to him, and he was warned not to remove the rubber stoppers until the time when the samples were to be taken. He was given full instructions as to the manner in which the samples were to be taken from the churns containing the milk of the whole herd, and then he filled in a paper stating the time at which the sample was taken, together with the temperature of the milk. The two sample bottles were sent, by the first available post, to Wye College for bacteriological and chemical analyses respectively.

Troubles arose at the beginning of the competition through the corks supplied with the bottles being inferior, and it was necessary to replace them with rubber corks. Another trouble was delay by post, necessitating at times supplementary samples. Some competitors filled the bottles with milk, which, when warm, was liable to force out the cork. Also in full bottles cream may become attached to the bottom of the cork, rendering a true chemical analysis impossible. There should always be about an inch of air-space between the top of the milk and the bottom of the stopper.

At the beginning of the competition it was suggested that it was a weakness to allow the competitors to take their own samples of milk, because they might "fake" them. Even if this method is open to criticism, it is really the only practical one of obtaining a large number of samples within a limited space of time. Several safeguards against "faked" samples were adopted. Any samples showing abnormal results were examined for preservatives, &c. Also surprise samples were taken at all the farms and the results of those examinations were compared with the results of the samples taken by the competitors themselves. Again, the score-card marks proved to be a further check. Not a single case of "faking" was detected.

At the end of each fortnight an interim report was sent to the competitors showing the total number of bacteria and the number of coliform organisms found per cubic centimetre of the sample submitted, together with the percentage of butter-fat it contained, and also the marks awarded for keeping properties. The above figures for every herd were given, so that a competitor could compare his own results with those obtained by other competitors, but the identification of each herd was hidden under a code number. Each competitor was told the number of his own herd only, so that he could not identify the herds of his neighbours. These reports were appreciated thoroughly by the competitors. The fortnightly report also included advice as to the best methods of cleansing utensils, the making of a home-made steriliser, the injurious effects of *Bacillus coli*, the causes of sour milk, the prevention of dust in the cowshed at milking time, and the way in which dust by spraying might be diminished. The first fortnightly return was not sent out until after the second series of samples had been received from all competitors, and so on. In this way all competitors received the same advice at a time when they all had submitted the same number of samples of milk.

Those farmers whose milk contained coliform organisms were advised to keep a watch for manurial contamination. The method of scoring for *B. coli* was as follows : Full marks for each sample of milk were 100, and if *B. coli* could be detected in 1 c.cm. of milk, 10 points were deducted, and by gradual stages up to such a point that if *B. coli* could be detected in 1/1000 c.cm. of milk, 40 points were deducted.

Similarly, in the total bacterial count if there were 500 bacteria or less in 1 c.cm. of milk no marks were deducted, and thence by gradual stages until a final point was reached where there were over 6,000,000 bacteria in each 1 c.cm. of milk, 70 marks were deducted.

The marks for keeping properties were awarded according to the number of days each sample remained sweet, without a taint and without clotting, when kept in an incubator at a standard temperature of 60° F. For each half day the sample remained sweet, starting from the time the sample was taken, two points were awarded.

For the percentage of butter-fat an average was taken of the analyses of the six morning samples submitted by each competitor. An average of 6 per cent. of butter-fat scored full marks (100), and three marks were deducted for every 0·1 per cent. below this figure down to 5·0 per cent. butter-fat which scored 70 marks. From 5·0 per cent. butter-fat downwards two marks were deducted for every 0·1 per cent. Therefore, at the end of the list, a sample showing 3·1 per cent. of butter-fat would score 28 marks.

The Results Obtained.

The results obtained were very interesting. The total number of samples of milk examined was 395, representing 11,731 gallons of milk. No less than 222 samples (representing 6300 gallons of milk) came up to Grade A milk standards for the number of *B. coli* and total number of bacteria of all kinds present, whilst 109 samples (representing 3250 gallons of milk) even came within the standards for certified milk. In other words, the 53 competitors between them were producing 3150 gallons of milk daily, and of the samples taken of this milk during the three months of the competition 54 per cent. came up to the Grade A standard, and 27 per cent. up to the certified milk standard for bacterial contents. This is a high commendation for Kent milk under the conditions named above. It will be remembered that the standard laid down in the Milk (Special Designations) Order, 1922, for certified milk is not more than 30,000 bacteria per c.cm. of milk, and no coliform organisms traceable in 0·1 c.cm., and that the standard for Grade A milk is not more than 200,000 bacteria per c.cm., and no coliform organisms in 0·01 c.cm. With respect to the keeping properties, a gradual improvement was noticed as the competition proceeded. Of the total number of 395 samples, 55 per cent. remained sweet for two and a half days from the time of sampling; 16 samples remained sweet for four complete days.

The average figures of butter-fat for individual herds ranged from 3·12 to 5·30 per cent., the average being 3·78.

Lessons to be Drawn.

Many valuable lessons were learned from this competition. It was proved that a large quantity of reasonably clean milk can be produced in Kent, and that expensive and up-to-date buildings are not essential for its production; they make it easier to produce clean milk but they are not essential. Plenty of water and close attention to small details are necessary. One little mistake may ruin what might otherwise have been an excellent sample—perhaps any one careless milker, one dirty cow or bucket, one dirty tap, or a dirty straining cloth might be the offender. The additional expense in producing reasonably clean milk does not take the form of additional capital outlay, so much as of extra time and trouble in getting the udders of the cows and everything else scrupulously clean. A man can clip the udders of 8 to 10 cows in one hour, and this should be repeated every 5 to 10 weeks. This operation does not cause chill in the udders. Another operation which saves time in the daily grooming is the clipping of the hair on the inside of the tail every few weeks. The only equipment necessary for grooming the cows is a wet brush and a currycomb for the tail and hindquarters, a strong cloth for the udders, some buckets of tepid water, and wrung-out cloths for wiping purposes. The udders should be washed separately from the tails and flanks, and a special bucket of water and cloth should be kept for that purpose. The operation of cleaning every cow under the above conditions will take two or three minutes each morning or evening.

As dust is such a great carrier of germs the spraying of the cowshed with water before milking is useful. With a knapsack sprayer this will take about five minutes. Frequent whitewashing of the cowshed is a great help. During the competition it was noticed that many of the milkers, with great pride, donned their white overalls, washed their hands, and examined their finger-nails before they started to milk. Partially covered milking or hooded pails proved valuable in preventing access of dirt to the pails during milking. The lack of proper cleansing of the dairy utensils was often the cause of bad samples of milk, and the need for a good supply of steam and water was well illustrated throughout. The value of a straining cloth is often over-rated. If a cloth is used which has not been properly sterilised since the last milking it may prove to be a fertile source of contamination. In that case a cotton-wool disc is preferable. A box containing 100 discs costs 2*s.* 6*d.* After use the discs can be discarded.

Cost of Cleanliness.

The chief extra cost in carrying out the above suggestions consists in the thorough sterilisation of the dairy utensils, but even this cost can be diminished by the installation of a home-made sterilising plant. It is a mistake to begin the cleaning process by scalding the pails and the cooler, because the albumin of the adhering milk will coagulate and render its removal more difficult. Cold water should therefore first be used to remove all traces of milk immediately after milking. The utensils may be left in cold water during the breakfast period. Then they should be washed with hot water and soda in order to remove greasy material. Countless organisms, however, still cling to the walls of the churns and pails. Only sterilisation can remove these organisms, but the two processes of washing and sterilisation should always be regarded as complementary one to the other. Steam is the most effective sterilising agent on a farm for the above purpose. The cooler is perhaps the most difficult article, excepting the milking machine, to keep clean.

An improvised sterilising plant may be used by an ordinary copper or portable boiler with a wooden lid, in the centre of which is a metal pipe 6 or 8 inches in length and 2 inches in diameter, in order to lead the steam from the boiler into the article to be sterilised. Mr. Garrad, the agricultural organiser for Kent, to whom I am indebted for much information in this paper, has estimated that the additional cost of carrying out all the above suggestions should not exceed 2*d.* per gallon—i.e., ½*d.* per quart of milk. In Reading farmers get 3*d.* per gallon extra for Grade A (tuberculin-tested) milk, and the retailer sells it at 4*d.* above the price per gallon of ordinary milk.

The Place of Raw Milk in the Diet.

At the end of this competition the Kent Milk Recording Society decided to publish a full report, to which I contributed a foreword, in the form of a handbook, 20,000 copies of which were distributed broadcast. Probably a greater section of the public are now alive to the need for a cleaner raw milk-supply than was the case several years ago, but unless care be taken misapprehension as to the best methods to be adopted may arise.

Clean raw milk is not only a perfect food, but it is by far the best form of milk if it can be obtained, and every effort should be encouraged to induce an increased consumption of such food, not only from a health but from an economic point of view. Opportunities for the contamination of milk arise at each stage of its journey from the cow to the consumer: soiled udders, the milkers' hands, the milk pail, the mixing vessels, the hands again, the carts, the shop, and so forth. It has been proved that the greater the cleanliness of the cow, the milker, the vessels, the cowshed, and the lower the temperature of the milk, the fewer are the bacteria present at the source of supply.

Any steps which might lead to a diminution in the consumption of raw untreated milk would be regrettable from every point of view. It would be equally regrettable if pasteurisation became general, as there might be a tendency for less careful measures to be adopted in order to obtain a cleaner milk-supply at its source. It is by no means certain that pasteurisation does not cause changes in milk which lessen its nutritive value, whether by destruction of vitamins or by the reduction of the lime contents which are so necessary for the building up of bone structure in young children.

I would therefore plead for, first, universal help and encouragement in the increased production of a cleaner raw milk at a reasonable cost; secondly, an increased consumption of such milk by a reassured public; and thirdly, a repetition and continuance of such competitions as I have referred to above. If such objects can be obtained, and I feel sure that they can be, a great step forward will have been taken towards the future success of the dairy industry and in an improvement of the general public health of the community.

A DESERVING CHARITY.

WE are happy to draw attention to the annual dinner of the Newsvendors' Benevolent and Provident Institution, which will be held at the Hotel Cecil, London, on Nov. 4th. The institution was established in 1839, and there are at present 79 pensioners, whose welfare is constantly borne in mind. Sick parents are sent to convalescent homes, orphan children are cared for in selected institutions, and financial help is given in cases of need.

"ALVUS ADSTRICTA."

Now that intestinal stasis is suggested as a predisposing cause of cancer, Dr. Isaac George writes from Esperance, West Australia, to remind us that he published in THE LANCET of Jan. 30th, 1904 (p. 345), a letter suggesting that the constant absorption of retained fæces must have an effect upon active cell life and produce changes leading to increased action and ultimate madness of rapid multiplication. "Every constipated individual does not get cancer; but does every person exposed to the tubercle bacillus get tubercle?" Only a certain number fall by the way.

AN IMPROVISED DRIP-FEED REGULATOR FOR CONTINUOUS SALINE ADMINISTRATION.

Dr. B. Gluck, resident medical officer at the Kent and Canterbury Hospital, writes: "Continuous rectal administration of saline has many advantages over other methods, both as regards effect and ease of giving. The apparatus can easily be improvised from a thermos flask and some glass and rubber tubing, but a visible drip-feed is essential. Both the Canny Ryall and the Laurie regulators are liable to break—generally just when required—and then may take some time to replace. The following can be made in a few minutes: A piece of glass tubing about 3 in. long is closed at one end with a small cork and a serum needle pushed through. A needle with tap, as used for subcutaneous saline, is an advantage, but otherwise the flow can be regulated to the required number of drops per minute by means of a screw clamp on the rubber tubing."

GREEN APPLES.

IT is accepted as an axiom by mothers and complacent neighbours that boys who eat large quantities of unripe fruit, especially apples, get colic. The belief is well founded, but on tradition and experience rather than on accurate knowledge of the exciting cause of the pain. The curious widespread acceptance of this sequence as inevitable, natural, and not dangerous—mothers can see a white-faced, guilty son flatten himself face downwards on the floor, or writhe on a couch with thighs strongly flexed, and remain undisturbed—has its advantages; for the family practitioner, if called upon to explain exactly why green apples give rise to colic, would consult in vain his learned books of reference. A physician of the new scientific school recently approached directly on the subject by an aggrieved victim murmured with great effect that it was a mystery. The much more frequent question from the irate parent, secretly annoyed with Providence for letting him down, as to how Freddy could have escaped consequences, can only be parried by a reference to Freddy's excellent inherited constitution; for it must be admitted that the reason why intestinal pain should so often follow on the consumption of unripe fruit is obscure. We know very little about the ripening process in fruit, and such information as we have hardly bears upon this subject. Incidentally, the very meaning of the term ripeness as commonly used is not a simple one; with regard to many fruits it is for practical purposes the stage at which we like to eat them—and that does not apply, for example, to medlars.

The main facts known about the ripening of the apple are that in the immature apple there is a quantity of starch which goes on increasing to a maximum, and then falls off to zero. On the other hand, the amount of sugar, chiefly lævulose, begins to increase as the starch diminishes, and for this reason starch is regarded as being the source of the sugar. From these facts we can get no help, since large quantities of starchy food can be taken with impunity by the young. Attempts have been made to incriminate the sourness or "acidity" of unripe apples. This certainly diminishes during the ripening process, but it is never great enough to warrant a suggestion that it could not easily be neutralised in the course of digestion. There remains a possibility that, on the analogy of the aperient action of salts of vegetable acids, such as tartrates and citrates in sufficient quantities, malic acid may have gripe-provoking properties, even when neutralised, but this does not seem very convincing. If the amount of malic acid in a given quantity of unripe apples were calculated, neutralised, and administered to a youthful volunteer, this point at least could be cleared up. In some fruits, again, there occurs a definite toxic principle, for example a glucoside, but there are no grounds for believing that unripe apples contain any such principle, and in any case it would be necessary to assume that it is spirited away or burnt up in the ripening process. Perhaps the least unconvincing explanation offered is a mechanical one—that the amount of indigestible matter per cubic centimetre is so much greater than in a ripe fruit, where the cells contain more water and pulp between their cellulose walls. During the ripening process there is, of course, an actual change in the cell-wall (the so-called middle lamella), which causes a loosening of the binding material between individual cells, and as the result of the softening characteristic of the process, the tissues form a mush much more readily than when the fruit is hard and unripe. In green apples there is almost a solid mass of indigestible matter, and however well masticated, it can scarcely fail to reach the bowel in hard, solid lumps.

We are hardly justified in suggesting to any young patient that he should consume salts of malic acid corresponding to 24 green apples, still less in commanding him to eat an equivalent number of green apples after they have been passed through a mincing machine and a sieve. The experimental method therefore cannot, as in so many clinical problems, be used to elucidate the matter. Dietetic faddists should note, however, that while a diet of unripe apples may be regarded as one almost wholly indigestible, it may be no more indiscreet than the habitual consumption of an almost wholly digestible diet, which leaves no residue behind to promote peristalsis. There must be a mean suited for each individual, which again will vary with his age and general state of health. It is for each one of us to ascertain for himself the relative proportion of digestible and indigestible food which goes to make up a satisfying, nutritious, and sufficiently laxative diet.

THE RESULTS OF TREATMENT IN SANATORIA.

To the Editor of THE LANCET.

SIR,—In your annotation (THE LANCET, August 2nd, p. 227) on the Medical Research Council's inquiry into the results of hygienic-dietetic treatment, as carried out in a well-run sanatorium, it is admitted that these results are difficult to assess. I should like pointedly to ask the question, Are we sure that sanatorium treatment is economically sound? Admitting that 80 per cent. of the best sanatorium patients are alive ten years after discharge, do we know how many of them would be dead if they had received equally skilled treatment at home? The Framingham figures suggest that there are ten active cases to each death from tuberculosis, from which it may be inferred that many cases recover undiagnosed and untreated. As a tuberculous subject myself, without prejudice against the sanatorium, I feel sure that I should not have got well so quickly if I had been separated from wife and children. It seems to me we need a carefully controlled experiment before it can be asserted how much it costs in sanatorium treatment to save a life.—I am, Sir, yours faithfully,

MEDICUS.

Sept. 11th, 1924.

⁂ The writer of this letter seems to us to belong to the small class of those who can carry out a course of strict hygienic-dietetic treatment without close supervision. To so do with success implies not only the material means but also the knowledge of the daily routine, and the will to carry through a régime of self-denial. At least 90 per cent. of patients at public sanatoriums lack the means to carry on at home, and of the remainder few, we believe, would be likely to see the matter through. In the experience of sanatorium doctors daily encouragement is an essential part of successful treatment. Outside sanatoriums, it would be hard to find any considerable body of practitioners competent or willing to undertake the supervision —ED. L.

PUBLIC HEALTH IN GAMBIA.

IN the official report for 1923 on Gambia, which is the smallest but the oldest possession of Great Britain in Africa, it is stated that no case of plague was reported. Cases of small-pox occurred from March to July, but owing to vaccination and immediate measures for isolation, the outbreak was not of a serious character. The general death-rate of the colony was 43 per 1000, and the birth-rate 26 per 1000. Only thrice in the last 20 years have the births been more numerous than the deaths. There were a great many deaths from tetanus. Infant mortality showed a slight improvement, there being 498 deaths as compared with 502 in 1922. During July, instead of the previous ten years' average of 7·6 inches, 27·49 inches of rain were recorded, and this was followed by 24·10 inches in August. About a quarter of the 400 acres covered by Bathurst (the chief town) is liable to annual flooding; in 1923 the proportion was greatly increased and the period prolonged. The standard of health in Bathurst was lowered, probably owing to the excessive damp. The increase of infant mortality from an average of 7 per month for the first six months of the year to 29 in July speaks for itself. There are five medical officers on the staff, one of whom resides in the Protectorate during most of the year. Out-patients treated at the Bathurst Hospital numbered 8712 and in-patients 596. There was an epidemic of influenza during October and November, but the case-mortality happily was small. A mother and child welfare committee has been started, and clinics in connexion with the same have been instituted at the hospital. Two additional African nurses have been appointed, and a new maternity ward has been erected.

The Diagnosis OF ACUTE ABDOMINAL ILLNESS IN CHILDREN.

A Post-Graduate Lecture given at St. Mary's Hospital Medical School on Oct. 6th, 1924,

BY GORDON BRYAN, *M.C.*, F.R.C.S. ENG.,
SURGEON (WITH CHARGE OF OUT-PATIENTS), ST. MARY'S HOSPITAL, PADDINGTON GREEN CHILDREN'S HOSPITAL, AND THE HAMPSTEAD GENERAL HOSPITAL.

To deal with so wide a subject as that of my lecture I must, of course, in the time at my disposal, confine myself to the consideration of a few only of its aspects; I have, therefore, attempted to select those rather of everyday interest and practical importance, but I discuss these with some diffidence, for I realise that your work as family practitioners gives you opportunities among children to some extent denied to the consultant.

It is obvious that there are certain differences between the ways in which abdominal conditions present themselves in adults and in children; in some respects the diagnostic problems of children are simpler, in other respects the difficulties are greater than in adults. In older patients, for instance, we place great reliance on the history and the subjective symptoms, which in children may be of little assistance. A detailed history, patiently elicited without leading questions, will often give the clue to an abdominal diagnosis; but a child is usually unable to give an accurate account of his illness, and may be too shy or too young to describe subjective symptoms at all definitely. In these matters the parent or nurse can be useful, but her description of the illness may be, and often is, indefinite and liable to exaggeration. The young patient, however, should always be asked to point to the pain, and he can usually be relied upon to localise this with some accuracy if it is in his abdomen.

THE ONSET.

In adults, again, the onset of acute abdominal illness is generally marked by symptoms which point directly to the abdomen, whereas there are many exceptions to this rule in children; in these early years most abdominal emergencies are due to lesions of the alimentary canal, and yet it is not uncommon for the most obvious symptoms of onset to direct attention elsewhere. For instance, the local condition may be masked by the intensity of early toxæmia, or the symptoms may indicate disease of the lower limb or of the urinary tract rather than of the intestines.

In his examination, the consultant who is a stranger to the child is in some degree handicapped; on the other hand, in arriving at a decision he may have some advantage over the regular medical attendant; with the latter the child is likely to be sufficiently familiar to give his confidence and allow a thorough examination, whereas with a stranger the little patient is likely to be shy and frightened, so that extra time must be allowed for quietly gaining his trust before the objective examination is commenced. The consultant, however, has an advantage in seeing him with a fresh and unbiased mind, for (as has often been pointed out before) frequent attendances for previous trivial ailments and repeated visits during the illness of the moment are apt to produce prejudice or indecision—the state of mind that has been called by John Fraser "clinical staleness"; so that we may impress on ourselves the necessity of the doctor being constantly on his guard against overlooking new developments of the disease, and the progress of signs and symptoms already noticed at previous visits. Also, the child's vivid memory of the first examination often causes sufficient fear to make subsequent investigations more difficult, and for this reason it is of supreme importance that the primary examination should be particularly thorough, and it should be our definite aim to arrive at any rate at a tentative diagnosis on this occasion. While the condition is in doubt, let me again lay stress on the importance at each visit of consciously trying to free one's mind of previous impressions, so as to avoid that biased judgment that I have already mentioned. Again, as a general rule, one may say that it is more important in children than in adults to diagnose acute abdominal disease promptly, because children are less able to withstand the effects of disease, and the delicacy of their tissues makes surgical intervention of special urgency in many cases. The general effects of acute abdominal inflammation are likely to be very severe, and toxæmia, shock, and collapse may reduce a child to a dangerous state in a very few hours.

OBJECTIVE METHODS OF EXAMINATION.

Of the objective methods of examination that are available in acute abdominal illness, in children, palpation of the abdomen and rectal examination are of most importance; in every case also the chest must be carefully examined and the urine must be tested. In palpating the abdomen three signs are to be borne in mind especially—the situation of the maximum tenderness, confirming any information already given by the patient as to the point of greatest pain, general or localised rigidity, and the presence of a palpable tumour.

To make a satisfactory *examination of the abdomen* of a child, especially the nervous or spoilt child, or one frightened by previous investigation, one must gain his confidence, and for this purpose one must have his full attention. It therefore often becomes necessary to exclude parents from the room during the objective examination; when called in as a stranger to the household one may feel a little diffidence in this matter, but tact and the presence of the regular practitioner usually make it possible for the consultant to examine the patient away from the relations. Even then it is not uncommon for children to resist examination so obstinately that palpation in the ordinary way is impossible, and in these cases very light anæsthesia—just sufficient to quieten the child but not enough to mask abdominal rigidity—will prove of the greatest value. In suspected intussusception also anæsthesia is often necessary for the palpation of a tumour or to exclude this possibility.

As to *rectal examination*, I feel that I cannot stress too strongly the value of this method of investigating a child's abdomen; it must always be employed in cases with acute symptoms pointing to abdomen or hip-joint. I have noticed sometimes that newly-appointed house surgeons at the Children's Hospital show some hesitation in examining the rectum of an acutely ill child, until it is pointed out how comparatively little discomfort is caused to a child by this procedure. Certainly it may be expected to frighten the patient at first, but if the finger is introduced slowly and then the examiner waits and reassures the child until he is quiet, a very thorough exploration of the pelvis can be made; the sphincter ani in childhood is usually lax and the small size of the pelvis and delicacy of the abdominal wall enable one to approximate the rectal finger to the hand outside very closely, so that the possibility of an inflamed viscus in the pelvis can be excluded with more certainty than is always possible in adult cases.

I must mention two important *aspects of the urine* examination that are of special importance in childhood: they are the possibility of acetonæmia and signs of pyelitis. A simple test for acetone is to add to the urine in a test-tube an equal quantity of a saturated solution of ammonium sulphate, and then a few drops of strong ammonia; a small quantity of a 5 per cent. solution of sodium nitroprusside produces a deep purple colour if acetone is present. In a case of pyelitis the urine is acid and opalescent; a drop taken from the centre of the specimen and examined with the microscope will show the presence of pus cells and *Bacillus coli* if the ureter of the affected kidney is patent.

DIFFERENTIATION.

The surgical possibilities of acute abdominal illness are less numerous in the early years than in adults, for, of course, we can exclude large groups of diseases common in adult life, such as malignant growths of the colon, chronic ulceration of stomach and duodenum, and chronic disease of the gall-bladder. There are, on the other hand, certain emergencies which almost exclusively belong to infancy and childhood, of which I may instance intussusception and the effects of certain errors of development of the alimentary canal.

Selecting, then, some of the acute illnesses of surgical importance which occur frequently among children, we must discuss appendicitis; peritonitis in its pneumococcal form; the later effects of abdominal tuberculosis, and especially intestinal obstruction and mesenteric adenitis; volvulus, intussusception, and strangulated hernia; iliac abscess, in addition to the variety resulting from appendicitis; acute pyelitis; abdominal influenza and simple colic; and acute acetonæmia or cyclic vomiting.

APPENDICITIS IN ITS VARIOUS FORMS.

The commonest surgical emergencies may be considered the most important, so I need make no apology for dealing first with certain aspects of appendicitis in children. The clinical picture varies according to the position that the appendix occupies in different cases; when it lies in its commonest position in the right iliac region we may expect a fairly typical picture in children, for they are less liable to the confusing influence of outside factors that often are present in adults, particularly concurrent disease elsewhere. The order of incidence of the early symptoms is of great importance in the diagnosis; Murphy called attention to the way in which these symptoms follow one another in the typical order of *midline pain, vomiting, right-sided pain,* and *fever.* In children, when dealing with the first attack as we so often are, there is frequently a history of preceding infection elsewhere, particularly of the tonsils. The initial pain is either generalised or localised to the epigastric or umbilical region.

Vomiting in children near the commencement of an attack of appendicitis is almost invariable, but it is sometimes absent when the appendix is retro-colic and shut off from the peritoneum, and occasionally in pelvic cases. In adults, on the other hand, this symptom is replaced by nausea or retching. Persistence of the vomiting in a child indicates distension of the organ, and should bring the risk of early perforation to our minds. When the pain shifts to the right side of the abdomen tenderness and some degree of rigidity will supervene. The early fever of appendicitis in the young is usually higher than in adults.

Of the physical signs the strongest positive evidence one obtains in the early stages is the palpation of a tender and swollen appendix through the abdominal wall; in children, when the appendix is in its typical situation, one can feel it with the flat of the hand in a large proportion of cases, even if rigidity is present. Patience may be required, for one often has to wait 15 minutes or more with the hand on the abdomen until the child breathes freely and partially relaxes his abdominal muscles; but the time is well spent, for one is enabled to advise immediate operation with a special feeling of confidence in such cases.

But it is not unusual for the appendix to lie in other situations, and the symptoms will vary accordingly. We must therefore briefly consider those cases in which the appendix lies in the pelvis, behind the termination of the ileum and its mesentery, behind the cæcum or ascending colon, and high up under the liver in association with an undescended cæcum.

In *pelvic appendicitis* there are certain special symptoms and signs, particularly in the early stages, which may distract the attention of the parents and even of the doctor from the alimentary canal, and delay correct diagnosis. Pain on micturition and frequency are common symptoms of pelvic appendicitis in the young, and may be so prominent as to lead to errors of diagnosis. I recall the typical case of a baby of 18 months who was admitted to hospital because he screamed with pain whenever he passed urine; this was the only symptom noticed and the possibility of vesical calculus had been suggested. On our way to see the case I told the dressers that appendicitis was the commonest cause of suddenly painful micturition in young children, and bimanual examination revealed the presence of a pelvic appendix abscess. Diarrhœa is another early symptom from the close relation of the inflamed organ to the rectum; it is apt to recur at a later stage if the condition goes on to abscess formation. Abdominal examination may give little assistance, but there is usually some tenderness above the pubis close to the midline.

Before leaving the subject of pelvic appendicitis, let me mention the obturator sign—pain produced by rotating inwards the flexed right thigh—for this brings to mind a certain type of onset in children, in which the possibility of the presence of appendicitis may be entirely overlooked. The child complains of pain in the right thigh or knee, or is noticed by the parent to be limping; on examination of the hip and knee nothing definite is found, but examination of the abdomen sometimes reveals slight hypogastric tenderness. Rectal examination shows the true nature of the case, for a swollen, tender appendix is felt on the right side of the pelvis. Several such cases have limped into my out-patient departments, and this condition must always be kept in mind when examining a child with pain of acute onset in the right lower limb.

The Retro-ileal Appendix.—Here the appendix lies behind the last part of the ileum and its mesentery, and causes the special symptoms of acute, though partial, obstruction of the small intestine. Vomiting is severe and persists to a later stage than is usual with the ordinary iliac type of appendix; the pain is spasmodic and the small intestine soon becomes distended. These two factors lead to early exhaustion and a special severity of general symptoms, as indicated by the loss of tissue fluids from the face and the rapidly rising pulse-rate. The maximum pain and tenderness are situated at or near the middle line, but there is often very little rigidity until a late stage of the illness, for the distended intestinal coils form a cushion separating the appendix from the abdominal wall and protecting it from palpation. This type of appendicitis is to be regarded as specially dangerous for several reasons—the diagnosis is difficult and apt to be delayed; in fact, a small retro-mesenteric abscess may not be suspected at all until it ruptures into the general peritoneal cavity. In this type, too, the protective omentum, so valuable in shutting off infection, is kept out of the way by the coils of intestine below it; again, the meso-appendix is short and œdematous and causes special technical difficulties in the removal of the offending organ and the control of its vessels. Lastly, there is a liability to the development of fæcal fistula during the after-treatment, and this is a less trivial complication in children than in adults. For these cases an adequate incision is particularly indicated, and consequently there may be more trouble than usual from sloughing of the abdominal wall and its resultant toxæmia.

With the *retro-cæcal or retro-colic appendix* there is usually present the congenital structure known as Jackson's membrane, which passes from the front of the cæcum and ascending colon to the right side of the abdominal wall, and separates the appendix from the general peritoneal cavity. Owing to this retro-peritoneal position of the inflamed appendix there may be no initial vomiting, and there is as a rule no rigidity of the anterior abdominal wall; the special sign to be looked for is rigidity of the loin in the ilio-costal space, and this region may show bulging and œdema if the condition goes on to abscess. The close relation of the appendix to the psoas muscle gives us a sign which should be examined for with the patient turned on to his left side; attempted hyperextension of the right hip causes pain in the right abdomen or loin.

The *high appendix*, lying in relation to the liver, congenital in form, and associated with an undescended cæcum and undeveloped ascending colon, causes tenderness and rigidity of the right hypochondrium, but these signs may be obscured if the inflamed viscus lies deep under cover of the liver; such cases may be difficult to diagnose from disease above the diaphragm, for there is often inflammation of the peritoneum covering this muscle, with resultant dyspnœa, activity of the alæ nasi, and cyanosis. A sign that is often of value in distinguishing this form of abdominal inflammation from pleuro-pneumonia is the eliciting of pain on the right side of the abdomen by pressure on the abdominal muscles of the left side. The rapidity with which, in a child, appendicitis develops into a dangerous stage cannot as a rule be estimated, depending as it does on the exact state of the inflamed structure; one is frequently impressed with the delicacy and thinness of the walls of a child's appendix, allowing perforation to take place a very few hours after the appearance of the first symptom.

CONDITIONS SIMULATING APPENDICITIS.

Next, I have to mention certain varieties of acute abdominal illness in childhood which may simulate acute appendicitis somewhat closely, and in one of them especially, operation would be disastrous. I refer next, then, to acute pyelitis, and to acute acetonæmia. I use the term *acetonæmia* advisedly, rather than cyclic vomiting, for the latter name rather conveys the impression of recurrent attacks with vomiting as the main symptom. Now, every year in the early spring, I make a point of warning house surgeons to be on the look-out for cases of acetonæmia, sent to hospital with a diagnosis of acute appendicitis. Such cases, often with no history of a previous attack, usually occur about March or April in children between the ages of 3 and 6 years, and the symptoms may simulate those of appendicitis very closely. The child is suddenly seized with severe vomiting and abdominal pain; on examination of the abdomen one finds general tenderness, due, perhaps, to the effort of repeated vomiting, and the distended cæcum and liver may be specially tender; it is this right-sided localisation of maximum tenderness that causes the simulation of appendicitis. There is fever, and the child seems seriously ill and exhausted; the facial appearance is characteristic—dark and shrunken under the eyes, with general pallor contrasting with the bright-red lips. If the tongue is inspected it is found to be coated, and at the same time the odour of the breath should be noted—the characteristic sweet smell of acetone. So marked is this smell in some cases that it can be noticed on entering the room or ward in which the patient lies. The child is lethargic but sleepless, and there is usually a history of loss of energy, anorexia, thirst, and constipation going back for some days previous to the onset of acute illness. In the more severe cases there is restlessness progressing to delirium and semi-coma. The diagnosis is to be confirmed by the finding of much acetone in the urine. Among these cases the most anxious are those in which local signs indicate that the appendix is involved in the distension of the cæcum, a result, of course, of the constipation; in several such cases one has been able to palpate the appendix, and very great may be the temptation to operate under the impression that the primary condition is appendicitis and the acetonæmia is secondary. There can be no question, however, that the safer policy is to wait, for an anæsthetic is, of course, definitely contra-indicated, involving the gravest risk of the disaster of delayed anæsthetic poisoning.

We know that a small degree of acetonuria is not uncommon in children with no clinical symptoms, but revealed by examination of the urine, and this is especially common in alimentary illness; should operation be urgently needed in such cases, every precaution must be taken, and gas-oxygen in combination with local analgesia is the method of choice.

Acute pyelitis occurs in girls; unlike appendicitis, fever is the initial symptom, there may be rigors, and toxæmia is early and severe. There is tenderness high up near the middle line of the abdomen, causing simulation of appendicitis. The diagnosis rests on examination of the urine, which is acid, opalescent, and contains pus cells and bacteria.

Abdominal influenza usually commences with vomiting, and headache is a prominent symptom. I only mention this illness to give a warning against mistaking the tenderness of the abdominal muscles for rigidity from underlying peritonitis.

An attack of *simple colic* and *constipation* in a child may give rise to anxiety, for the symptoms may simulate appendicitis; the typical order of incidence of symptoms is, however, absent, there is no true rigidity, and tenderness disappears between the attacks of colic. The diagnosis is confirmed by the rapid subsidence of symptoms after the application of a hot fomentation to the abdomen and the evacuation of the bowel by an enema.

Inflammation of the ileo-cæcal lymphatic glands frequently occurs in children and causes a transient illness that may very closely resemble appendicitis. The patient is subject from time to time to attacks of acute abdominal pain, with vomiting, and right iliac tenderness and rigidity; the glands can be palpated as an indefinite mass protected by the rigid rectus muscle—a mass that cannot, as a rule, in the early stages, at any rate, be diagnosed from the tumour that is formed by an inflamed appendix wrapped round by omentum. So similar are the two conditions that operation is usually carried out, whereby the true nature of the condition is revealed. In cases seen on the first day of the illness exploration is the safest policy; if, however, the case has been kept under observation without operation for two or three days, mesenteric adenitis can be diagnosed by the fact that the signs and symptoms tend to remain unaltered during this time, whereas in acute appendicitis they advance or recede.

Iliac abscess may arise from a variety of causes; one form is due to inflammation of lymphatic glands causing an abscess immediately above Poupart's ligament, and if on the right side this simulates an appendix abscess; it is, however, possible to diagnose it by the absence of peritoneal symptoms, the presence of enlarged femoral or inguinal glands, and possibly the finding of the primary focus of infection either in the form of a septic abrasion or furuncle or a recently healed scar.

Pneumococcal Peritonitis.—In children it is the primary form of pneumococcal peritonitis with which we are concerned, and the cases fall into two classes: those of extremely acute onset and rapid progress leading to an early fatal termination, and those of less acute onset resulting in a pelvic abscess. The disease affects girls over the age of 5, who almost invariably belong to the poorer classes, and is probably due to the infection gaining access to the pelvic peritoneum through the genital tract, at any rate, in the less acute cases. The more acute ones are possibly infected through the blood-stream; in the latter class of case there is a sudden onset of acute toxæmia with abdominal pain, vomiting, and diarrhœa. So severe is the illness that the child may be delirious and even comatose in a few hours, and rapid drainage of the peritoneum offers the only hope of saving life. In the subacute form of the disease there are diarrhœa, gradually increasing fever, and signs of peritonitis in the lower part of the abdomen. An abscess becomes localised, filling the pelvis and gradually rising above its brim. Sometimes these cases are so chronic that tuberculous peritonitis is simulated, the abscess reaching as high as the costal margin and pushing the intestines up under cover of the ribs; these cases may be distinguished from tuberculous peritonitis by the absence of shifting resonance, and the fact that in spite of complete rest in bed the disease progresses, as shown by the rising hectic temperature and gradual increase in size of the abdomen.

Gonococcal peritonitis occasionally occurs in young girls; the illness has an insidious onset and closely resembles the subacute form of pneumococcal peritonitis; the diagnosis rests on the history or signs of vulvo-vaginitis and possibly the identification of the specific organism.

Intestinal Obstruction.

Turning now to intestinal obstruction, apart from defects of development which cause symptoms immediately after birth, there are four conditions of special interest and importance in childhood, *intussusception*, *volvulus of the small intestine*, obstruction from the *adhesions* of old tuberculous peritonitis, and *strangulated inguinal hernia*. The typical picture of intussusception in infancy is too well known to you to need comment here, but when no tumour can be felt the diagnosis is often difficult. During the first few hours of an attack of acute entero-colitis with bleeding from the rectum, intussusception may be suspected and somewhat difficult to exclude; in addition to the passage of blood, there is screaming from colic, and abdominal palpation is rendered inconclusive by tenderness. The diagnosis rests on the absence of the typical intermissions in the spasms of pain, the absence of a tumour, and the fact that the blood is bright red and accompanied by loose fæcal material instead of forming, by admixture with mucus, the characteristic dark-red jelly of intussusception. In doubtful cases an anæsthetic should be given in order that a thorough search for the typical tumour may be made.

The specially difficult cases of intussusception are the enteric and the colic forms, and these often are diagnosed too late for successful treatment; in the former variety, the vomiting is severe and continuous, there is rapid collapse, the appearance of blood is delayed, there is no loss of normal resistance in the right iliac fossa, and it is often very difficult to feel a tumour owing to its comparatively small size and the fact that it may be hidden away under the liver. The rare condition of retrograde enteric intussusception must be borne in mind, and in this condition there is no blood and mucus in the rectum. Colic intussusception may take a subacute form, with less severe general symptoms, as for several days there may be no obstruction to the passage of fæces; careful palpation will, however, reveal the presence of the tumour and clinch the diagnosis.

The most serious difficulty in the diagnosis of intussusception is the simulation of this condition by cases of *Henoch's purpura* in which bleeding into the wall of the bowel takes place; the patient then may have acute abdominal symptoms with partial obstruction, there is a tumour in the iliac fossa due to the infiltration of the bowel with blood, and blood and mucus are passed by rectum. The condition is commoner in boys above the usual age for intussusception, and its recognition depends on the finding of other signs of purpura, such as scattered petechial hæmorrhages of the skin, subcutaneous bruising, and a history or signs of hæmarthrosis, while the abdominal tumour lacks the typical shape and mobility of an intussusception. The diagnosis, may, however, be a matter of the greatest difficulty.

Obstruction by Adhesions.—Apart from intussusception and congenital defects of the intestine, there are a limited number of causes of acute intestinal obstruction in childhood; antecedent tuberculous peritonitis is responsible for most of the cases. Here the obstruction is rarely complete in the first attack, and there is nearly always a history of previous illnesses with vomiting, colic, and constipation, relieved after a few hours by the passage of large loose stools. If such cases have to be operated on when obstruction is complete, a serious problem arises, for in a child enterostomy offers small hope of recovery. Our aim must be, by diagnosing such cases early, with the assistance of X rays, to operate in an interval between attacks, and perform some variety of short-circuiting operation whereby the affected coils of intestine are excluded.

Volvulus in children differs from the type met with in adult life by affecting the small intestine; it occurs where there is a long mesentery with a narrow attachment. In a typical case the attack is brought on by some sudden movement, and the symptoms are those of high small intestine obstruction—severe and persistent vomiting, spasms of acute pain, and rapid collapse; it is not unusual for one or more stools to be evacuated from the intestine below the obstruction. Poynton has described cases in which acetonæmia was a predominating feature, and he shows the risk of diagnosing primary cyclic vomiting; in his cases there had been previous similar attacks, due probably to torsion of the intestine which was relieved naturally. The difficult feature of these cases is the absence of abdominal signs; owing to the rotation affecting so high a part of the small intestine there is no distension, and the poisoned and collapsed condition of the patient masks the tenderness due to the obstructed coil.

True *strangulation of a hernia* is rare in babies and small children, for though irreducibility and obstruction occur fairly commonly, the blood-supply of the intestine is rarely affected seriously. The tender tense hernia could hardly be overlooked, and the vomiting and constipation indicate the obstruction. Occasional difficulty arises in distinguishing an irreducible omental hernia from inflamed inguinal glands; in the former it is usually possible to trace the swelling into the abdomen, with the latter one can find the healed or unhealed skin lesion responsible for the infection. In doubtful cases we have the satisfaction of knowing that the diagnosis is not of great urgency owing to the absence of true strangulation; also, few of these cases need operation, for most strangulated herniæ in young children will slip back if the colon is emptied by an enema, the child is partially suspended by the legs, and a hot fomentation is applied to the swelling.

An Address

[ABRIDGED]

ON

THE IDEAL TOOTH.

Delivered at the Royal Dental Hospital, Leicester-square, London, on the Opening of Session and Presentation of Prizes, Oct. 1st, 1924,

By Sir ARTHUR KEITH, M.D. Aberd., F.R.C.S. Eng.,

HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

On a recent occasion I had the pleasure of listening to an address given by an eminent statesman to an audience made up, for the greater part, of medical men. He was in the happy position of being able to say that at no point of a long and busy life had he required help from either physician or surgeon. Such an experience must be exceptional; few men and women do reach the age of 70 without calling for medical aid. I should think that 90 out of every 100 have settled, or should have settled, several doctors' bills before reaching the age of 70. The statesman said nothing of his teeth, but if he reached the age of 70 without having to seek the aid of a dental surgeon, then his lot was better than falls to 999 out of every 1000 septuagenarians. If we were to make a survey of the dental conditions which prevail at the present time in Great Britain, confining our attention to the mouths of men and women of the age of 60 and upwards, I do not think we should find even one in a thousand who retains a full undamaged outfit of teeth, and who can boast that on no occasion has there been need of dental aid. I think that a strict survey would show us that, as a general rule, we have to visit our dentist five times for every occasion we have to call in medical aid. It would appear, then, that of all the structural systems which make up that wonderful piece of machinery, the human body, the dental system is that which is most liable to break down.

NATURE AS DESIGNER AND WORKMAN.

There was a time when the design and workmanship of our bodies commanded the unstinted admiration of anatomists. In these modern days, however, there has arisen a critical school, founded by the late Prof. Elie Metchnikoff, which calls in question both the design and workmanship of the human body. Metchnikoff held that there were glaring imperfections in the contrivance of many of its parts. He cited as an instance man's great bowel, in which are included both cæcum and appendix. He held that, so far as modern man is concerned, the presence of a great bowel was a mistake; it merely served as a filth sink; it was a constant menace to health and the cause of misery in untold millions of lives. If a liability to become disordered, to become the seat of pain and a source of misery, is a reliable index of imperfect design and workmanship of an organ or of a system of organs, then Nature's attempt to fit modern man with an efficient dentition is an utter failure. I am putting the matter from a Metchnikoffian point of view; as will be seen in the sequel I hold a brief for Nature—both as designer and workman.

It is far from uncommon to meet with men and women who in their sanest and soberest moments, when their judgments are undisturbed by pangs of pain, give utterance to the conviction that Nature's "teeth are more bother than they are worth." They are convinced that it would be better for human health, happiness, and efficiency if our jaws retained the edentulous condition of birth and that we should be better to depend, from infancy to old age, upon artificial dentures than upon Nature's efforts. Such critics are prepared to pay golden guineas for artificial teeth rather than accept Nature's two sets as a free gift. Yet, on the production of these two sets—a milk set of 20 members and a permanent set of 32—52 all told—Nature has lavished her ingenuity to the utmost. It would be strange, indeed, if Nature after spending millions of years in perfecting her dental handiwork should now turn round on modern man and undo in his body her endless endeavours to reach perfection. Is it possible that city-living man is doing something which frustrates her best efforts to give him a healthy body?

Disharmony between Structural Outfit and Civilisation.

Those who criticise Nature's dental workmanship can cite many pieces of evidence in support of their contention. They may instance the baby fretting, slobbering, restless, as it cuts its first teeth: why should the eruption of teeth be attended by pain? Then, when the milk teeth have cut and are in use, half of them, before they have done their full duty, become the subjects of caries. The teeth, which we ironically name "permanent," render their owners open to many kinds of trouble. When they cut they may find the jaws too small to give them a place in a regular series; upper and lower teeth may be so badly placed that they fail to make proper contacts in the acts of biting and chewing. When the "permanent" teeth have come into use, half of them fall victims to caries before the age of 50 is reached. If they escape caries they may fall victims to pyorrhœa, or gumboils may form at their roots. The four final molars—the wisdom teeth—may be suppressed altogether, or if formed, they may fail to erupt or erupt painfully long after youth is past. The rarest sight in modern mouths is a tooth worn to its neck from use. When modern man enumerates his dental woes, it is clear that either Nature is neglecting him or he is neglecting Nature. On whichever side the fault may lie there is, without doubt, a grave disharmony between the structural outfit of man's body and the conditions with which modern civilisation has surrounded it.

The Artificial Tooth and the Natural Tooth.

Now, every form of fault-finding or criticism is idle unless we can say exactly where the fault lies and how it can be mended. Let us for a moment conceive ourselves as occupying Nature's place, and, endowed with all her powers, given the problem of evolving an ideal kind of tooth for modern man. We expect a tooth which is proof against every form of infection. The modern dentist has solved this problem; artificial dentures are liable neither to caries, pyorrhœa, nor gumboil. We expect a tooth which is painless under all circumstances; the modern dentist has solved this problem too. The ideal tooth must be so shaped as to perform its work efficiently. In this respect the modern dentist can teach Nature nothing, for he moulds artificial teeth as closely to Nature's shapes as his art will permit him. The teeth of an ideal set must be so placed that upper and lower meet in perfect apposition. The modern dentist can avoid Nature's glaring errors of malplacement, but he cannot rival her accuracy when she works in her normal mood. We expect the ideal tooth to be durable—to be made of material which will withstand 70 years of wear or more. The modern dentist has solved this problem too. The ideal tooth must be made of a material or materials, which are not only durable, but are free from brittleness; they must be able to withstand all legitimate strains and stresses without fracturing, cracking, or breaking. In this respect Nature's materials—a core of tough dentine, crowned by a covering of hard enamel—outclasses all modern inventions. She has hit on ideal substances and arranged them in our teeth in an ideal manner. Further, the ideal tooth has to be firmly fixed in the jaws, and must give the feeling when placed in our mouths of being, not a foreign thing, but an intrinsic part of our bodies. The best of artificial dentures falls far short of this ideal, yet it is one which Nature, in her normal moods, can attain with certainty. The most eminent and skilful of modern dentists would never dream of claiming that his best can rival Nature's best. I cannot believe that the day will ever come when men and women will prefer an artificial denture to Nature's outfit, except under the pressure of necessity.

The Function of the Pulp.

In our search for an ideal dentition, then, we cannot conceive any better than that invented by Nature. Can we suggest any improvement in detail? The first which occurs to us is to get rid of the pulp and of the pulp cavity. This is exactly what the dentist does when caries has eaten into the heart of a tooth and set up intolerable pain. Why has this operation not been forestalled by Nature? I have before me now the jaws of men who lived in Babylonia some 6000 years ago. The crowns of the teeth are almost worn away from use, and yet the pulp cavities are not exposed; as erosion wore the crowns down, the odontoblasts of the pulp laid down secondary dentine until the cavities became obliterated. Why do these dentine builders need the pressures and strains of use to set them to work? Why are the teeth furnished with pulp? The answer is that a tooth is a living thing; every element of it needs nourishment—even the enamel prisms. The pulp is Nature's means of keeping the tooth flooded with the elements needed for the sustenance of life. If the cavity of a tooth is filled then all the nourishment which can sustain a tooth has to reach it through the periodontal membrane. A stopped tooth is not a dead tooth, but it is one which is imperfectly nourished, unfit for hard wear, and liable to atrophy and to infection. For the full health of a tooth, a pulp cavity is a necessity. Odontoblasts are sensitive to wear and react by the formation of sound secondary dentine. But Nature has not discovered a method of making them react to the insidious invasion of caries. If Nature is put to it, I dare say she may discover a method of arresting invasion of caries by the formation of secondary dentine. Meantime it has to be admitted that she has not made this discovery, and that with the death or destruction of its pulp a tooth loses its full condition of health.

The Nerves of a Tooth.

Why should teeth be so richly supplied with nerves? We know the curse these nerves bring to us when teeth become diseased, but where is the blessing which should accrue to us from this rich nerve-supply in health? It does not seem to me that we give a satisfactory reason for the presence of such nerves by saying that they are protective—that a sensitive pulp prevents us from neglecting or from abusing our teeth. Sir James Mackenzie holds that pain, when it occurs as the result of disease, is usually a manifestation of a disordered reflex. What reflexes could be centred in or round a tooth? One can conceive, although there is no evidence on the point, that end-organs or receptors of reflexes which regulate the muscles of mastication may be situated in the periodontal membrane, but one does not expect such receptors to occur in the pulp cavity. Yet they may, for when we bite or chew hard or tough substances there must be a certain degree of deformation of the tooth and of the pulp cavity, and such deformation may be registered by nerve terminals in the pulp. An experience with which we are all familiar throws some light on this point. A tooth may pass into a condition where the application of heat or of cold will elicit a severe toothache. When heat or cold is applied to a tooth there must be an expansion or contraction of its body, extremely slight in degree, yet sufficient to render its pulp cavity just too large or just too small for its contents. One would suppose that to adjust the size of the pulp to its cavity there must be a local vaso-motor reflex which accommodates the pulp to the size of its cavity. When a tooth becomes diseased this reflex is lost or disordered, and hence the application of heat or of cold causes stretching or compression of the pulp and thus elicits pain. Even if we succeed in explaining how pain is elicited in toothache, we are still far from giving a satisfactory answer to the question, Why is pain elicited? All we can say at present is that if a tooth is to be healthy and durable it must have a pulp, and if it is furnished with a pulp, then it must be provided with nerves and the price of nerves is a liability to pain. If we accept Nature's dentition, we must be prepared to purchase its overwhelming benefits at the risk of suffering.

NECESSITY OF STUDYING NATURE'S METHODS.

In our search for an ideal tooth for modern man we cannot conceive anything so good as Nature's best. We cannot suggest any improvement in her designs, materials, or manner of production. Why, then, should she serve modern civilised man so indifferently while the wild apes of the jungle enjoy her superior workmanship? The apes' teeth, so long as their natural lives are led, are almost proof against caries and against pyorrhœa; not absolutely but nearly. It is only when the crowns are worn down and the formation of secondary dentine is inadequate that they become liable to gumboil and root abscess. Yet apes never brush their teeth; their children attend no dental clinic. Whereas we poor human beings, take what pains we may, find ourselves the subjects of the grossest forms of dental disorders. Is it that Nature is really scamping her work so far as the teeth of city-living man is concerned, or is it that city-living man in his ignorance is not supplying Nature with the materials—or materials in the proper ratio and condition—out of which she has been accustomed to fashion teeth? Discoveries which have been made by Dr. and Mrs. Mellanby seem to show this is the case. We are supplying the clay and withholding the straw which she needs for the fashioning of her dental edifices. Our bad teeth are not due to Nature's bungling, but to our ignorance of her ways. If we are to have sound teeth we have to study Nature's methods with infinite patience, and humour her by supplying the materials and conditions under which she can do her best work. Even human workmen demand such terms.

It is often said that degeneration has overtaken our teeth because we do not use them as early man did. It is most probable that use and wear harden the texture of a tooth, for teeth are living things, and all living things react to use. Use may be a condition of preservation of the fully erupted tooth, but I do not think that lack of use through countless generations has caused the reduction in the size and number of teeth in modern man. Since her very earliest endeavours to fashion mammalian teeth Nature has brought them into use after their chewing crowns were fully formed; if there was inheritance of the effects of use, crowns should be formed with their tips worn off. The units of a dentition are assembled, just as are the units of a motor-car—all fully finished and ready to fit into place before they are ever put in movement. Tooth after tooth erupts to find perfectly fitting opponents ready to come into contact with them. We do not know the machinery which Nature uses to coördinate the parts of her dental mills, but it is certainly not the mechanical one of usage.

AN OBSCURE MECHANISM.

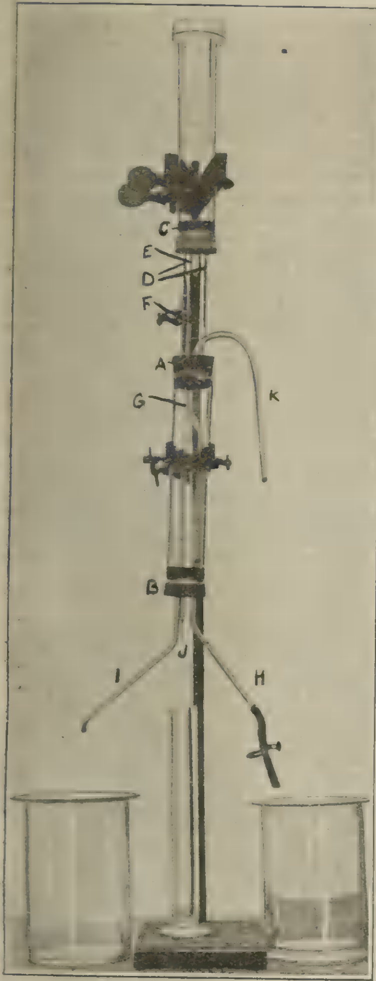
There is some mechanism at work in the human body which tends to weaken the jaws and teeth as it strengthens the powers of the brain. The exact nature of this mechanism remains obscure. One could conceive a developmental correlationship between brain and teeth—one which exercised a restraining influence on teeth as it favoured an increase of brain. One, however, is tempted to suppose that the reduction of the teeth has not been brought about in this way, but by the increased powers of the brain altering the conditions under which the development and growth of man's body takes place. The discovery of fire and of cooking must have wrought a revolution in the conditions of human life—and subjected the teeth and the whole alimentary tract of evolving man to a new set of conditions, demanding fresh adaptations. We do not know at what period of man's evolution the discovery of fire was made. In Rhodesian man, one of the most primitive and simian of human types yet discovered, massive robust-looking teeth are ravaged by caries and dental abscess. His remains lay in the utmost recess of a great cave which was chokeful of animal bones—apparently the residue of human feasts. It does not seem too much to suppose if we are to account for the condition of the teeth of Rhodesian man, that he was suffering, just as we are, from the early experience of new conditions. Had he learned the secrets of fire and been seduced into the use of cooked food? Perhaps, like us, he blamed Nature for his misfortunes.

CONCLUSION.

Thus our search for an ideal dentition leads us to the conclusion that the best conceivable, the best obtainable, is that which Nature has to offer every one of us. Only we must realise that she lays down conditions, conditions which have to be discovered as well as accepted and observed. We have to abandon our present mood—the Metchnikoffian mood—in which we lay down conditions which we expect Nature to observe. We expect her to keep up the standard of her dental workmanship when we swamp our own bodies, as well as the developing tissues of the fœtus, and infant, with substances she finds difficult to handle and utilise. We demand that she will adjust at once her adaptational machinery to our new modes of living and blame her when she fails to respond. It is all so childish and so unreasonable! All she asks of us is that we shall understand the method of her workmanship and the materials which she requires in the fashioning of teeth. And if we patiently apply ourselves to her behests I, for one, believe she will give us the dentition we deserve.

AN APPARATUS FOR USE IN THE SIGMA REACTION.

By JOSEPH W. BIGGER, M.D.Dub., F.R.C.P.Irel.,
PROFESSOR OF BACTERIOLOGY, UNIVERSITY OF DUBLIN.



In diluting the antigen for use in the Sigma reaction it is necessary to allow saline to drop into the alcoholic solution at constant rate. In place of the floating syphon used by Dreyer and Ward, I have, for the past 18 months, used the following apparatus, and I believe that it is more satisfactory and less troublesome than the floating syphon. It consists of two cylinders (about 20 by 4·5 cm.), the lower of which is provided with two rubber bungs (A and B), the upper with one (C). Through holes in A and C pass two glass rods (D) which help to stabilise the apparatus. The upper surface of C is cut so that the fluid in the upper cylinder is able to drain out completely through the short glass tube E. This is connected by a rubber tube F, on which is a screw clip, with the tube G. This passes through A and reaches almost to the bottom of the lower cylinder. The surface of the bung is cut in the same way as C to drain the cylinder through the glass tube H, which ends in a rubber tube with a spring clip. Through B also passes the tube I, the height of which in the cylinder can be varied. J is the terminal portion of a dropping pipette. The curved tube K admits air into the lower cylinder but excludes dust.

The upper cylinder is filled with saline, which flows through E, F, and G, and rises in the lower cylinder. When it reaches the level of the top of the tube I, it flows through this and escapes. The clip on F is adjusted until the saline which is dropping from J also drops slowly from the end of I. So long as the upper cylinder contains saline, the head of fluid acting on J will remain constant. Using a graduated cylinder and a stop-watch, the rate of dropping from J is adjusted by pushing the tube I further through B, or by withdrawing it until exactly 34·0 c.cm. of saline drops from J in 4 min. 30 sec. Once adjusted the apparatus works accurately when required without further alterations of I. When the antigen is made, the upper cylinder is emptied by opening the clip on F, and the lower by releasing the clip on H. It is allowed to drain for a few minutes. The entry of dust, when the apparatus is not in use, is prevented by an inverted Petri dish which covers the opening of the upper cylinder. When again required, the whole is rinsed through with sterile saline a couple of times, and is then ready for use.

ON INFLUENZAL ARTHRITIS.

WITH NOTES OF THREE CASES OF INFECTION OF THE KNEE-JOINT IN CHILDREN.

By DAVID NABARRO, M.D., F.R.C.P. Lond.,
DIRECTOR OF THE PATHOLOGICAL DEPARTMENT AND
BACTERIOLOGIST, HOSPITAL FOR SICK CHILDREN,
GREAT ORMOND-STREET;

AND

J. F. H. STALLMAN, M.B., B.S. Lond.,
F.R.C.S. Eng.,
CLINICAL ASSISTANT, LATE SURGICAL REGISTRAR, AT THE
ABOVE HOSPITAL; SURGICAL REGISTRAR, LONDON
TEMPERANCE HOSPITAL.

Joint infections complicating or following influenza are one of the rarer surgical complications of this disease, since after an extensive search through a very large literature we have discovered only three recorded cases in which the influenza bacillus was actually obtained in pure culture from the joints.

Slawyk [1] (1899) recorded a case in a baby with an abscess on the dorsum of the right hand and an arthritis of the left ankle-joint. This case terminated fatally with meningitis. The organism was obtained in pure culture from the pus and cerebro-spinal fluid.

The second case was recorded by Dudgeon and Adams [2] (1907) in a baby with suppurative arthritis of the left elbow- and right hip-joints, causing gross disorganisation and necrosis. This case ended fatally with meningitis, the organism being obtained in pure culture from the cerebro-spinal fluid and the affected joints.

Henry [3] in 1912 recorded a series of nine cases of "meningitis due to hæmophilic organisms—so-called influenzal meningitis?" In one of these cases, a child of 16 months, the knees and ankles were swollen, but on the following day, when the child was admitted to hospital with obvious meningitis, the joint swellings had disappeared. Death occurred within a week, and post mortem an influenza-like bacillus was obtained from the brain, spinal cord, heart blood, liver, kidney, and lungs. Two guinea-pigs were inoculated with 18-hour-old cultures of the organism; the one inoculated subcutaneously was unaffected, the other, inoculated intraperitoneally, died in 24 hours, and the organism was recovered from the peritoneum and heart blood. There are two further points of bacteriological interest in this case: (1) The fluid obtained by lumbar puncture during life is said to have shown badly-staining intracellular diplococci, which were regarded as meningococci; and (2) cultures on blood-agar showed well-marked filament formation after 18 hours' incubation, and after 24 and 30 hours tangled masses of filaments. Maitland and Cameron [4] (1921) refer to a case in which the *Bacillus influenzæ* had been isolated from the blood and infected knee of a child by Dr. Erb, of the Hospital for Sick Children, Toronto. No clinical details are given.

Other cases have been described as complications or following influenza, but they lack conclusive bacteriological support. The general opinion seems to be that the joint infections are usually non-purulent.

Schmieden [5] (1919) says that frequently there are only passing effusions which continue for a few weeks and are then spontaneously absorbed. In other cases some callous thickening and contractures may result. He compares them to mild forms of gonorrhœal arthritis, and Prader [6] (1920) described four cases of acute synovitis with rarefying osteitis having the type of gonorrhœal arthritis.

In contrast to the non-purulent cases, several cases of suppurative arthritis have been described, some ending in gross disorganisation of the joint or joints involved, with necrosis of their bony parts, some even terminating in death. Some of these have been streptococcal infections.

Prader describes five such cases of suppurative arthritis, two of the knee-joint, one ending fatally in spite of amputation, and three of the hip-joint, needing resections of the head of the femur, two ending fatally. He also described three cases of sero-purulent exudation into the knee-joint, resolving on aspiration, one with slight subluxation, but streptococci and diplococci were found. Roello [7] (1921) recorded two cases of suppurative arthritis in children, 13 months and 3 years old respectively. In one case of the right shoulder-joint, Gram-negative diplococci were found; from the other, of the left elbow- and right hip-joints, a diplo-streptococcus was isolated. Complete recovery took place in the former, in the latter 2 cm. shortening of the leg remained. Khàrina-Mannucci [8] (1919) reports a case of suppurative arthritis of the right shoulder-joint in a baby of 10 months, recovering from influenza with respiratory complications. A short bacillus resembling *B. pyocyaneus* was grown. Complete resolution occurred with an autogenous vaccine, without recourse to operation.

Since during an influenza epidemic almost any unexplained febrile attack is very often diagnosed as influenza, it is conceivable that some of such cases are caused by absorption of toxins from some unrecognised source of infection, possibly the teeth, and, giving rise to symptoms clinically resembling influenza, be diagnosed as such; a secondary lesion complicating or following would be thus termed "influenzal." It seems scarcely scientific or justifiable to ascribe lesions to influenza unless the specific organism be obtained from the pus or be found in the primary illness.

Clinical Records.

In all three of the cases recorded in this paper the infection was of the knee-joint, and it is remarkable that two of them were admitted on the same day. A Gram-negative bacillus resembling *B. influenzæ* was obtained in pure culture from all of them, and in the third case it was also isolated from the cerebro-spinal fluid.

Onset.—In only one case (Case 3) was the joint infection preceded by an illness which might have been influenza; in this case there was a cold a week before which developed into pneumonia. The other two developed as an ordinary acute synovitis of the knee-joint with sudden onset of pain in the joint, general ill-health, and feverishness.

Type of Infection.—On admission they presented the appearance of an acute synovitis, raised temperature, and a distended and acutely tender joint. On exploratory puncture thick creamy pus was obtained in Cases 1 and 3, and thin pus with a faint greenish tint in Case 2. It may be noted that the exudate into the meninges of Case 3 found post mortem was of a pale green colour. On opening the joints a suppurative synovitis was found without any erosion of cartilage or other joint structure. In Case 1 on admission there were no bony changes, but subsequently an osteitis developed on the outer side of the lower third of the femur, and a later skiagram showed this in process of healing. A skiagram of Case 2 showed a doubtful area of rarefaction on the inner side of the femoral diaphysis. Case 3 showed no bony changes.

Treatment.—Three methods of treatment were carried out. Case 1 was treated by the Carrel-Dakin method of irrigation. Case 2 was opened and the joint washed out for 10 minutes with 2 per cent. chloramine in saline and then closed. Case 3 was at first treated by repeated aspirations, but no benefit arising, the joint was opened and drained. All three methods of treatment were successful; Case 3 developed cerebro-spinal meningitis from which she died, but as far as the joint was concerned, the treatment was successful. Case 2 had a smoother convalescence than Case 1, which may be correlated with the observed difference in pathogenicity of the organisms recorded below. The treatment of election would seem to be aspiration or opening the joint, washing it out and closing it. If the temperature continues high and the general condition does not improve, and if the local signs do not subside and bacteria are still found in the joint exudate, then opening and drainage would be indicated, but this as a primary operation does not appear to be the method of choice.

Results.—Complete resolution of the joints occurred in the first two cases, and the post-mortem on Case 3 showed that, as far as the joint was concerned, this was progressing towards complete resolution.

Case 1.—Joan C., 1 year, 11 months, was admitted under Mr. H. A. T. Fairbank to the Hospital for Sick Children, Great Ormond-street, on May 4th, 1923.

History.—Commenced five days ago with pain in the right knee. Very restless with pain throughout the night, and very feverish. Joint very tender. No vomiting, bowels constipated. There was no history of any injury to the knee.

Past History.—Child much under weight. Breast-fed until 11 months old.

Condition on Admission.—Temp. 102°; pulse 160; respirations 32. Right knee-joint distended, hot, and tender. No movements allowed. A skiagram showed no bony changes.

Operation (May 4th, 1923).—Joint opened on outer side, counter incision made on the inner side. Thick creamy pus evacuated. Joint washed out with 2 per cent. chloramine in saline and Carrel-Dakin tubes inserted. May 24th: A skiagram showed osteitis on outer side of lower third of femur. 27th: Wounds healed except for a small sinus. Sinus probed and pus and blood-clot evacuated. 29th: Temp. 100°–102°. Wound probed and foul blood-clot removed. June 5th: Temp. normal, sutures removed. 14th: Skiagram showed area of rarefaction on outer and anterior aspect lower third of femur. Periosteum raised. Cortex a little more dense than at last examination, indicating a healing process; considerable swelling in joint. 18th: Discharged, wounds healed.

Pathological Investigation.—Pus greenish-yellow. Films stained by Gram's method showed numerous minute Gram-negative bacilli. No tubercle bacilli were found. Cultures on blood-agar and on T.B.E.* agar furnished a good growth of minute colonies, almost invisible to the naked eye, in 24 hours. Films of this growth showed pure Gram-negative bacilli morphologically like the Pfeiffer's bacillus. The whole of a 24-hour culture was emulsified in saline and injected intraperitoneally into a guinea-pig, which succumbed in 18 hours. The organism was recovered in cultures from the peritoneal exudate, the spleen, and the heart blood. A second specimen of pus from a "hæmatoma" or abscess was examined on May 27th, 1923, and again this bacillus was found to be present. A similar very fine growth was obtained on T.B.E. agar, which showed long and short Gram-negative bacilli and filaments. A culture on agar smeared with blood remained sterile.

Jan. 17th, 1924: The mother reports: "Perfect movement in the leg, no pain or swelling."

Case 2.—Charles M., 8 months, was admitted under Mr. G. E. Waugh to the Hospital for Sick Children on May 4th, 1923, with a history of three days irritability and crying and left knee drawn up.

Condition on Admission.—Temp. 101°; pulse 160; respirations 38. Left knee flexed, tender swelling lower third left femur, pitting on pressure. No signs of fluid in the joint.

Operation (May 4th).—Outer side lower third of femur explored, bone found healthy. Wound closed. Knee-joint aspirated, thin pus with faint greenish tint removed. Joint opened outer side of patella, about two ounces pus evacuated. Joint irrigated with 2 per cent. chloramine in saline for ten minutes. Wounds closed with interrupted salmon-gut sutures, dry sterile dressing applied. Leg put on single Thomas splint with extra knee-flexing iron, and slung. May 11th: Temp. normal. 25th: A skiagram showed a doubtful area of rarefaction inner side femoral diaphysis. 29th: Wounds healed. June 18th: Discharged, wound soundly healed. Limb straight, but flexion restricted to 20°

Pathological Investigation.—The pus was similar in appearance to that in the first case and contained many minut Gram-negative bacilli. Cultures on agar, blood serum, an on T.B.E. agar remained sterile, but a profuse growth o minute dewdrop-like colonies occurred on agar smeared wit blood. Morphologically the bacilli resembled the influenz bacillus. A 24-hour old culture was injected into a guinea-pi as in the first case, but the animal remained aliveand well.

Jan. 18th, 1924: The mother writes: "He has full movement of the knee, and is running about the floor quite well.

Case 3.—Ruth W., 1 year, was admitted under Mr. Twistington Higgins on Nov. 8th, 1923.

History.—Seen a week previously, and had a cold whic developed into pneumonia five days ago, since has been ver ill. Yesterday painful swelling of right knee noticed, pa on touching and on movement. More swollen and shin to-day. No vomiting, bowels opened.

Condition on Admission.—Temp. 103°; pulse 16 respirations 40. Child very ill. Consolidation upper half right lung. Uniform swelling of right knee-joint, no fluctu tion detected. Nov. 8th.: Aspiration of knee-joint. Sma quantity of gelatinous fluid withdrawn. 16th: Chest clea Temp. still raised. Joint distended chiefly in suprapatell pouch. Aspiration: 3 c.cm. thick pus obtained fro the suprapatellar pouch. 17th: Temp. 101°; pulse 14 respirations 36.

---

* Tryptamine-blood-extract agar (Cole and Onslow's medium

Operation.—Joint opened outer side of patella. Thick pus obtained, localised to suprapatellar pouch. Joint drained. An autogenous vaccine was prepared and a dose of 10 millions given on Nov. 23rd.

Nov. 30th: Wound healed, but continuing swinging temperature. Signs of meningitis developing. Further doses of the vaccine were given on Dec. 1st and 6th, but the meningitis was then fully established and death took place on Dec. 9th.

Post-mortem Examination.—Right knee-joint: Operation wounds healed; signs of previous inflammation in suprapatellar synovial pouch. Brain and cord: Cerebro-spinal meningitis. Ventricles distended and full of a mixed watery and creamy exudate. Gram-negative bacilli were present in the pus and grew in cultures.

Pathological Investigations.—The gelatinous fluid drawn from the knee on Nov. 8th contained a few mononuclear cells. A culture in broth remained sterile after four days' incubation. 16th: The pus aspirated contained many minute Gram-negative bacilli, some of them intracellular. No tubercle bacilli found. Cultures on agar remained sterile. 17th: Many Gram-negative bacilli present in the pus and clot, also some larger forms. Cultures made on blood agar and chocolate agar; on blood agar there was a profuse growth in 24 hours of minute colonies, practically invisible to the naked eye. Films showed long and short forms of a Gram-negative bacillus, morphologically like the Pfeiffer's bacillus. The chocolate agar was sterile after 24 hours, but after 48 hours a growth similar to that on the blood agar was present. Some of the pus was injected intraperitoneally into a guinea-pig, but the animal showed no lesions after one month. The cerebro-spinal fluid was examined on several occasions. It had the usual characters of the fluid from a case of so-called influenzal meningitis. The sediment showed many cells—practically all polymorphs—and Gram-negative bacilli (resembling Pfeiffer's bacillus), some of them intracellular. Morphologically long and short Gram-negative bacilli were present. A little of the purulent sediment from the cerebro-spinal fluid (Nov. 30th) was injected intraperitoneally into a guinea-pig. The animal was ill the next day and found dead on the following day. Post mortem there were signs of peritonitis, but the organism was not recovered from the exudate.

We are indebted to Mr. Waugh, Mr. Fairbank. and Mr. Higgins for their kind permission to publish these cases.

Comments (J. F. H. S.)—1. Without bacteriological proof the relation of joint lesions with influenza is unsatisfactory.

2. The joint lesions are usually monarticular but may be multiple, and may occur weeks or months after the primary illness.

3. The general opinion seems to be that the majority of joint infections complicating or following influenza are of a benign nature, ending in complete resolution in most cases, a little thickening, and slight deformity remaining in a few. Severe suppurative arthritis may occur in a minority of cases, and some of these may prove fatal.

4. The best form of treatment is that based on conservative lines in the simpler forms—viz., fixation in a suitable splint (such as a modified Thomas splint) and slinging. Consideration must be given to movements and subsequent function as soon as the acute stage has subsided. Aspiration of the joint, repeated if necessary, is better than open drainage, which should only be carried out when the clinical signs and bacteriological indications show that aspiration is not proving successful. Opening the joint, irrigation, and primary suture may be carried out in place of aspiration with equally beneficial results. Severe suppurative arthritis must, of course, be treated on the usual lines as when occurring in other circumstances.

5. The prognosis in the simpler forms is good both as to life, &c., and as regards the function of the joints involved.

Comments (D. N.).—These three cases are of considerable interest on account of their rarity. As regards prognosis, two of our three cases recovered, while the third died of meningitis, the involved joint, however, being apparently well on the road to recovery. Two of the three previously reported cases (Slawyk, and Dudgeon and Adams) succumbed to meningitis and general infection with the *B. influenzæ*. In one case the affected joints, post mortem, showed definite inflammation of the synovial membrane with the presence of turbid fluid in the joint; whereas in the other case the affected joints were disorganised and the bones necrosed.

Ætiology of Influenzal Meningitis and Arthritis.

As regards the ætiology of these cases of so-called influenzal meningitis and arthritis, there is still considerable difference of opinion as to the identity of the isolated bacillus with Pfeiffer's bacillus. Pfeiffer[9] (1893) originally described the influenza bacillus as being found only in the nasal passages, and regarded the post-influenzal nervous symptoms as being toxic in origin. He could not demonstrate the organism in the blood. Since then, however, several observers have demonstrated the bacillus in the blood and in the exudate and pus of "influenzal" cerebro-spinal meningitis. Morphologically these bacilli resemble the original Pfeiffer bacillus, but in artificial cultures the former tend to produce more filamentous forms than the latter. On animal inoculation, too, some differences have been recorded. Whereas the Pfeiffer bacillus is not very pathogenic for animals, and when injected in massive doses may kill by toxæmia and not by septicæmia, the organisms isolated from so-called "influenzal" meningitis cases have often been found pathogenic for animals. These observations have induced some investigators (Cohen[10] (1909), Henry [3]) to regard the organism of meningitis as being different from Pfeiffer's bacillus, which, however, it resembles closely in morphology and staining reactions. The case reported by Slawyk does not bear out this view. He states that the influenza bacillus grown from the cerebro-spinal fluid showed longish filaments in culture and that Pfeiffer himself identified the cultures as *B. influenzæ*, nevertheless 0·5 c.cm. of cerebro-spinal fluid killed a guinea-pig in half an hour after intravenous injection, and a two-day-old broth culture killed a guinea-pig in three days. After the diagnosis was made the *B. influenzæ* was found in all parts of the body, including the blood.

The work of recent observers (Blake and Cecil,[11] Parker,[12] Huntoon and Hannum,[13] McIntosh [14]) has shown that whereas cultures from solid media, even in massive doses, may be non-pathogenic, liquid cultures are often markedly pathogenic for rabbits, mice, guinea-pigs, and monkeys, and that even the filtrates of such cultures may be highly toxic. With this toxin, too, an antitoxic and agglutinating serum may be prepared from rabbits. Cohen has attempted to differentiate the meningitis strains from the true influenzal strains of the bacillus by agglutination and protection experiments. Other observers, however (Maitland and Cameron [4] (1921), Bell [15] (1920), Valentine and Cooper [16] (1919), Povitzky and Denny [17] (1921), Coca and Kelly [18] (1921), Yabe [19] (1921)), have been unable to group strains of *B. influenzæ* either morphologically or serologically—the morphological variations are very marked and do not appear to correspond to variations in agglutination, and serologically most strains appear to be distinct when tested by agglutination and absorption methods.

From the evidence available it would appear justifiable to conclude that the strains of *B. influenzæ* which have been isolated from the lesions in influenza (pneumonia, bronchitis, rhinitis) and its complications, meningitis, arthritis, &c., and from healthy carriers, all form one group of organisms which may show marked differences in morphology, in their pathogenicity for animals, and in their agglutination and absorption reactions.

REPORT ON TWO CASES OF DIRECT INJECTION INTO THE HEART FOR ARREST OF HEART BEAT DURING ANÆSTHESIA.[1]

By W. B. HOWELL, M.D. McGill,

CHIEF ANÆSTHETIST, ROYAL VICTORIA HOSPITAL, LECTURER ON ANÆSTHETICS, McGILL UNIVERSITY, MONTREAL.

Fifty years ago, Schiff, a German physiologist, found that the heart could sometimes be started again after it had stopped beating; other physiologists confirmed his observations. It was, however, some years before surgeons applied Schiff's method to human beings and were able to recall to life some of their patients, apparently dead on the operating table. Of recent years massage of the heart has been displaced by direct injection. The following are two cases in which the heart stopped beating but was set going again by means of the direct injection of adrenalin.

Case 1.—The patient was a man, aged 30, who had had pulmonary and intestinal tuberculosis for seven months. During this time his weight had sunk from 168 to 102 lb. At the time of operation there were signs of active disease in both lungs, but especially in the left, where there was believed to be a cavity.

On Jan. 27th, 1924, he was given nitrous oxide and oxygen with McKesson's apparatus. The administration was begun at 10.20 A.M. Dr. Archibald, assisted by Dr. Scrimger, opened the abdomen, and proceeded with a short-circuiting operation. The anæsthetic was given for an hour and fifty minutes, during which time the breathing became shallow and stopped temporarily two or three times, the colour becoming rather dark. Each time the nitrous oxide was turned off and pure oxygen given under moderate pressure. On each occasion breathing was resumed spontaneously, the colour quickly becoming pink. At 11.30 the pulse dropped to 90, and was markedly irregular. Ten minutes later the irregularity had disappeared and the rate risen to 130. As the operation proceeded the patient's colour became somewhat paler. At 12.10 P.M., just after the completion of the bowel anastomosis, breathing stopped, the colour became very pale, and the pulse could no longer be felt. Pure oxygen was turned on and used to inflate the lungs rhythmically under moderate pressure. After a pause a deep spontaneous inspiration was taken, and after another considerable pause this was repeated. The oxygen was continued, and artificial respiration performed by rhythmical compression of the lower thorax. About three minutes after breathing had stopped Dr. Archibald introduced his hand into the abdominal cavity for the purpose of massaging the heart. It was then felt through the diaphragm as a flaccid bag, obviously paralysed in diastole. The ventricles were rhythmically compressed, the left hand exerting counter pressure outside the chest wall. Only the lower half or two-thirds of the ventricle could be grasped. After about two minutes' massage without response a syringe for direct injection was called for. By this time the appearance was that of death, the pupils being widely dilated. Probably another minute elapsed before the syringe was produced. Dr. Scrimger then injected 1 c.cm. of a 1 in 1000 solution of adrenalin in the region of the heart. As no response could be felt by the hand in contact with the heart it seemed doubtful to Dr. Archibald if the needle had been pushed into the heart muscle. Consequently another dose of ½ c.cm. of a 1 in 1000 solution was injected about a minute later, but without result. After another minute Dr. Scrimger inserted the needle again. This time Dr. Archibald felt that it had passed through the middle of the ventricles into the pericardium beyond. The needle was then partly withdrawn and 7 minims of pure adrenalin solution injected into the heart. After about ten seconds pulsation was felt, at first weak but rapidly growing stronger, until within a minute the ventricle was beating with considerable force, and becoming steadily more rapid. The whole time during which the heart had been stopped must have been nine or ten minutes. The rate was now between 80 and 90 and the contractions very strong. The pulse could be felt in the wrist and temporal arteries, and the colour had returned to the face and lips. Artificial respiration was continued for several minutes before the patient took a spontaneous breath. The breathing was at first shallow, with considerable intervals, but soon became regular and deep. The lungs were now found to be full of coarse râles, and the breathing sounded, to the bystanders, as if there were a good deal of fluid being churned up in the larger air-passages. It was concluded that œdema of the lungs from the temporary stopping of the circulation had developed. Dr. Archibald percussed the chest, and noting the obliteration of the heart dullness suggested the presence of pneumothorax.

The patient was returned to his room. The head was kept low and the administration of oxygen continued. His systolic blood pressure was 120. He was quite unconscious and rather restless, showing a tendency to throw his arms about and move his head quickly from side to side.

Dr. Moffat now examined his chest and diagnosed pneumothorax. A needle was therefore introduced and the air slowly aspirated. This had to be repeated frequently as the air seemed to collect rapidly and cause respiratory difficulty. In spite of the use of oxygen and cardiac stimulants the patient died without regaining consciousness at 5.30, 5 hours and 20 minutes after his heart had first stopped beating. Permission was obtained to remove the lungs for examination. It was impossible to find the place where the air had gained access to the pleural cavity. It was probably at the apex where the surface of the lung was torn by the breaking down of adhesions during removal. There was no sign of injury to the lung by the needle used for the injection.

Case 2.—This patient was a man aged 71, who had ha his prostate removed by Dr. D. Mackenzie on Jan. 5th. He lost a good deal of blood at the operation, and his convalescence was slow and unsatisfactory. On Feb. 29th during a cystoscopic examination, he was attacked b severe pain in the abdomen, accompanied by weakness an faintness. The pain continued, and the next morning h was feverish, and vomited. Enemas were ineffectual. Th abdomen was distended and rigid. A diagnosis of peri tonitis was made and he was taken to the operating room His general condition was very grave. At 11.20 on March 1s he was given nitrous oxide and oxygen by means of McKesson apparatus. The peritonitis was found to b due to a leak at the base of the bladder. The bladder wa drained, and cæcostomy performed to relieve the distensio of the bowels. At about 11.45 the patient's colour suddenl changed, he became very pale, and the pulse disappeare from the temporal artery and wrist. Breathing, after very short interval, stopped too. The nitrous oxide wa at once turned off and pure oxygen given with rhythmica pressure. At the same time artificial respiration by com pression of the lower chest was commenced. The lips ha become white and no heart's impulse could be felt. Som adrenalin solution (½ c.cm. of 1 in 1000) was therefor injected into the heart through the fifth intercostal spac The result was almost dramatic. The heart's impulse an the pulse at once returned, the colour improved, and withi a short space of time spontaneous breathing began, at firs at intervals of about 10 seconds, but soon becoming fast and regular. Probably the time during which the pul disappeared was not more than two minutes. After breathi had become re-established the sounds were noticeabl moist as if there were abundant froth in the air-passage To check this secretion he was given atropine, gr. 1/15 hypodermically. On his return to his room his pul showed signs of failing again, and he was given adrenali (1 in 1000 solution) hypodermically with considerab

benefit. He did not regain consciousness until 6 o'clock in the evening. Afterwards his convalescence was slow but continuous.

Commentary.

In this, unlike the first case, the heart was not felt through the diaphragm, but the reasons for believing it had stopped were equally strong. There was the cessation of pulse, apex beat, and respiration, the appearance of the patient's face, the fact that when the needle was pushed into the heart no movement was felt, the prompt appearance of œdema of the lung when the heart recovered, and the protracted interval before the return of consciousness. In such emergencies it is very difficult to estimate time exactly, but the duration of the intervals between the various events was noted immediately—in consultation with Drs. Archibald and Scrimger in the first case, and with Dr. Scrimger in the second.

One of the most noticeable features in such cases is the length of time the nervous system takes to recover as compared with the heart. There is always a long period of unconsciousness afterwards. This is well shown in a case reported by W. M. Mollison.[2]

A boy of 6 was given a mixture of chloroform and ether for the operation of removing tonsils and adenoids. Just as it had been completed pulse and respiration stopped. By means of direct injection of pituitrin into the heart and massage through an opening in the abdominal wall, the heart was started again after 13 minutes. The patient was unconscious for seven days. For ten days he had choreic movements and symptoms of brain irritation. He eventually recovered.

Another interesting feature is the prompt appearance of œdema of the lung, apparently due to the arrest of circulation. In looking over the records of such cases in the literature of the last few years one finds the condition of the lung mentioned very rarely. Prus noticed it in his experiments on dogs, two out of 12 dying from this cause during the first hour after revival.

The chief lesson to be learned is the necessity for immediate injection of adrenalin into the heart. When breathing stops during anæsthesia the first thing is to ascertain the condition of the heart, for no amount of artificial respiration will oxygenate blood which is not circulating. Time spent in giving hypodermic injections, hot applications, &c., is merely compromising the chances of recovery. The actual injection is apparently harmless. Many post-mortems have been done on patients in whom cardiac injections have been given, but in none has damage to the heart been recorded, whereas damage to the heart muscle which was inconsistent with life has been revealed at post-mortems after cardiac massage. The needle should be inserted into the fourth intercostal space at the upper edge of the fifth rib, close to the sternal border, or else one finger's breadth inside the left border of relative heart dullness. By the first route, the right, and by the second, the left ventricle is reached. By either the internal mammary artery is avoided. The needle is known to be in one of the cavities of the heart by the escape of blood when the stylet is withdrawn. If the heart is much distended with blood it may be of advantage to let some escape. It would seem most rational to make the injection into the heart muscle itself. One French writer advises injection into the cavity of the heart, believing that absorption through the lymphatics of the endocardium can take place in time.[3] The injection can be conveniently made by means of a spinal puncture needle. Other substances than adrenalin have been used, but none have proved so satisfactory. The best method of artificial respiration is by means of the intra-tracheal insufflation of air. Sylvester's method has the drawback of hampering the heart by means of pressure on the lower thorax.

My thanks are due to Dr. Archibald and to Dr. Scrimger for permission to report these cases and for the help they gave me in recollecting the course of events.

INFECTIVE ENDOCARDITIS IN CONGENITAL HEART DISEASE

INVOLVING THE PULMONARY ARTERY.

By H. E. A. BOLDERO, B.M.Oxf., M.R.C.P. Lond.,
PHYSICIAN TO THE EVELINA HOSPITAL; MEDICAL REGISTRAR, MIDDLESEX HOSPITAL;

AND

D. E. BEDFORD, M.B., B.S. Lond.,
MEDICAL REGISTRAR, MIDDLESEX HOSPITAL.

THE occurrence of infective endocarditis in congenitally malformed hearts, although emphasised in text-books of medicine, is nevertheless infrequently met with in hospital practice. The association is interesting, first because it is rare, and second because it throws light on the origin of infective endocarditis in general.

The recent investigations of Lewis and Grant[1] have demonstrated the importance of congenital defects of the aortic valves in the causation of subacute bacterial endocarditis; and we propose here to consider the relationship of the more common congenital malformations to infective endocarditis involving the pulmonary artery. Endocarditis, simple or vegetative, is less common at the pulmonary valves than in any other situation, pulmonary incompetence being the rarest valvular lesion. Statistics based on post-mortem findings published by Osler (209 cases),[2] Horder (118),[3] Washbourn (100),[4] Cowan and Ritchie (70),[5] Glynn (47),[6] Abrahams (39),[7] Libman (19),[8] comprising 602 cases of infective endocarditis, show involvement of the pulmonary valves in 30 cases only, an incidence of 5 per cent. From an analysis of 198 consecutive cases of infective endocarditis from the post-mortem records of the Middlesex Hospital, we found the pulmonary valves affected in nine instances, or 4·5 per cent. Three of the nine cases had congenitally deformed hearts.

Apart from congenital malformations, the pulmonary valves are most frequently affected in gonococcal endocarditis, and in puerperal and traumatic septicæmias. Rheumatic endocarditis of the pulmonary valves is almost unknown, and therefore one is able to consider the development of the infective process in this situation, as it were, in virgin soil.

With regard to the relative frequency of the various malformations associated with pulmonary infective endocarditis, Newton Pitt[9] found among 21 collected cases: (1) patency of the ductus arteriosus in three cases; (2) defects of the interventricular septum in ten cases; and (3) pulmonary stenosis in eight cases. We have found descriptions of 36 cases in the literature; patent ductus arteriosus was present in 13 cases, patent interventricular septum in 12, pulmonary stenosis in 7, patent auricular septum in 6, defects of the pulmonary valves in 2, and stenosis of the conus arteriosus in 2.

1. *Patent Ductus Arteriosus.*

According to Libman this is the most important defect connected with infective endocarditis. The following interesting case has recently occurred which was under our observation for over two years, and in which an autopsy was performed.

A male of 29 years was admitted to the Middlesex Hospital under the care of Dr. C. E. Lakin in June, 1921, complaining of pain in the legs and of feeling unwell. According to his mother he had had "rheumatism in childhood," and diphtheria at 7 years of age. He had always been delicate and "suffered with his heart," and had never been able to do ordinary work. He was of average physical development, but mentally backward. There was no cyanosis and no clubbing of the fingers or toes, but the complexion was highly coloured. Physical examination revealed a greatly enlarged heart with some bulging of the præcordium, and a diffuse pulsation most marked in the second left interspace. A pronounced thrill with maximum intensity over the pulmonary area was palpable throughout the cardiac cycle. On auscultation a very loud harsh bruit was heard over the præcordium and at the back of the chest, most marked in the second left interspace near the sternum; the bruit continued throughout systole and diastole with systolic intensification. In addition a loud " bang " was audible over the pulmonary area during systole. X ray examination showed the heart to be considerably enlarged to the right, as well as to the left. The aorta was dilated, but there was no evidence of aneurysm. The electrocardiogram showed great increase in amplitude of the ventricular deflections, with an inverted T wave in lead 1, but no other abnormality. The systolic blood pressure was 200 mm. Hg, and the diastolic 90. The blood picture showed a polycythæmia of 8,375,000 red cells per c.mm., with a colour index of 0·58. The Wassermann reaction was negative. The patient had slight irregular fever for the first three weeks only, and he was discharged after two months, considerably improved in general condition. A tentative diagnosis was made of patent ductus arteriosus with superadded endocarditis.

He was readmitted in June, 1923, after being under observation in the out-patient department periodically. His general condition had deteriorated, and symptoms of cardiac failure were now present. There was œdema of both legs and moderate enlargement of the liver. The spleen was palpable. On examination of the heart much the same physical signs were found, the lungs, however, showing bubbling râles and rhonchi all over the chest. The temperature ranged from 99° to 102° F.; the pulse from 100 to 120 per minute, and the respirations were increased to 40 per minute. The blood examination now showed marked anæmia, the red cells being 2,700,000 per c.mm., and the leucocytes 9700. No tubercle bacilli were present in the sputum. The patient's condition did not improve under treatment and he died one month after admission.

Post-mortem Examination.—The heart was greatly enlarged and both ventricles were hypertrophied, the left ventricular muscle being 9/10 of an inch thick, and the right 4/10. A massive warty vegetation, measuring $1\frac{3}{4}$ by 1 inch, was found completely filling the lumen of the pulmonary artery, extending from the valves to slightly beyond the bifurcation, and firmly adherent to the anterior wall of the vessel. The ductus arteriosus was patent, measuring 3/5 inch (1·5 cm.) in length, its lumen being partly filled with small warty vegetations which protruded from the aortic orifice of the canal. Two small calcified areas were present in the wall of the aorta; one just below the ductus opening, the other on the convexity of the aorta directly opposite the ductus opening. On passing a probe along the canal from the aortic aspect, it was found to be buried in the mass of vegetations in the pulmonary artery previously described. The pulmonary cusps were the seat of extensive vegetations, growing mainly from the ventricular surfaces. Between the right anterior and posterior cusps was a mass 1 inch long extending upwards into the pulmonary artery and downwards into the ventricle, causing great distortion of the posterior cusp. The aortic cusps were covered on their ventricular surfaces with luxuriant vegetations; in addition, both the mitral and tricuspid valves showed small recent deposits, situated mostly on their auricular surfaces. The lungs showed brown induration and great œdema, but no infarction. The liver weighed 40 oz., and on section many small inflammatory areas were seen, which microscopically proved to be foci of round-celled infiltration around branches of the hepatic artery. Sections of the kidneys revealed a mild degree of embolic glomerular nephritis.

The above case is a good example of subacute bacterial endocarditis engrafted on a congenital lesion. The infective process appears to have commenced at the pulmonary end of the ductus arteriosus and to have spread along the wall of the pulmonary artery, finally involving the valves.[*]

Hamilton and Abbott[10] have described a similar case, and have collected ten others from the literature. In their own case a large oval mass of vegetations was present on the wall of the pulmonary artery, but the valves had escaped. From a careful histological study they conclude that the process originated in the pulmonary end of the ductus as a result of invasion of the intima at the point of maximum strain, and not as an embolic infection via the vasa vasorum. Of their 11 cases the wall of the pulmonary artery was involved in all, the wall of the ductus in nine, the wall of the aorta in seven, while the pulmonary valves were affected in two cases only. In a similar case described by Horder[3] the aortic valves were diseased, in addition to the mass of vegetations on the wall of the pulmonary artery which started at the ductus but did not extend to the pulmonary valves.

The fact that the pulmonary valves so frequently escape make it quite clear that the process originates in the artery wall, most probably at the site of the ductus. This extensive endarteritis would appear to be peculiar to the pulmonary artery. In this connexion the case described by Weber and Fürth,[11] of a man, aged 27, who had had gonorrhœa, is of interest, in that the process occurred without there being a congenital defect or valvular lesion. In several of the above cases the artery was involved as far as the medium-sized branches, and in four case mycotic aneurysms were also present.

2. *Defects of the Inter-Ventricular Septum.*

The post-mortem records of the Middlesex Hospital since 1860 contain seven cases of infective endocarditis in which this lesion was present. In one case a congenital aperture in the undefended spot was the seat of a mass of vegetations which projected into the right ventricle and involved the septal cusp of the tricuspid valve. In another case stenosis of the conus arteriosus was also present, the constricted portion being surrounded with fibrinous vegetations. In a third case the stenosed orifice of an aberrant pulmonary artery was fringed with vegetations, while the valves were healthy. Yet another case of especial interest was one described by Dr. Thompson in 1877, in which two perforations of the ventricular septum at the site of an aneurysmal bulging were fringed with vegetations, which had spread into the conus arteriosus and involved the pulmonary valves, causing incompetence. These perforations were considered as acquired, but from their situation in the membranous part of the septum it seems possible that a congenital defect was originally present. Five saccular aneurysms occurred on branches of the pulmonary artery. The specimen is preserved in the museum of the Middlesex Hospital.

In the cases reported in the literature, vegetations were commonly found around the margin of the aperture, spreading to the ventricles, either contiguously or forming deposits on the wall opposite. The pulmonary, and frequently the aortic, cusps were also involved. Where one side of the heart alone is affected, paradoxical embolism may occur.

3. *Pulmonary Stenosis.*

In our analysis of 198 cases of infective endocarditis there is no instance of its occurrence in this congenital lesion. This relative infrequence is probably due to the fact that pulmonary stenosis has a more serious prognosis than the other two lesions we have discussed; and therefore subjects are less likely to reach the age at which infective endocarditis is most common. . Dickinson[12] described an interesting case of its occurrence in a male of $4\frac{1}{2}$ years, in which thrombosis of the pulmonary artery resulted.

Considerations.

There is as yet, we feel, no wholly satisfactory explanation of the fact that infective endocarditis of the left side of the heart is far more common than that of the right. The study of the inception of the infective process is simplified by considering it as it occurs in congenital lesions, more especially of the pulmonary valves, for thus can rheumatic damage be excluded.

The common lesions—namely, defects of the septa and patency of the ductus arteriosus—might predispose to infection of the pulmonary valves in the following ways:—

1. The rise of blood pressure produced in the lesser circulation exposes the pulmonary valvular apparatus to increased strain. That this does occur is certain, as evidenced by the enlargement of the right ventricle and dilatation of the pulmonary artery so often present. In cases of patent ductus arteriosus Abbott[13] has found atheromatous changes in the pulmonary

---

[*] The case, and subsequently the specimen, were shown by Dr. C. E. Lakin at the Medical Society of London. (Med. Soc. Trans., vol. xlv., p. 29.)

artery, and even aneurysm of this vessel has been described (Durno and Brown).[14] There is, however, little reason to suppose that this increased pressure is a factor in the predisposition to infective endocarditis. In other conditions, where a high pulmonary pressure occurs, there is no special liability to infective lesions. Stokes[15] observed that in cases of atheroma and dilatation of the pulmonary artery, secondary to emphysema, the valves were usually unaffected. Again, in the cases of atheroma and dilatation of the pulmonary artery described by Rogers[16] as occurring in India, and which he attributes to syphilis, the valves were normal. Furthermore, in the parallel instance of the aortic valves in cases of hyperpiesis with raised systemic pressure, infective endocarditis is unusual.

2. The thickened endocardium usually present at the site of congenital apertures forms a suitable soil for bacterial invasion. Horder considers this factor of prime importance, and points out that in the case of septal defects vegetations occur round the margins of the aperture and on the wall of the ventricle at the point upon which the stream of blood impinges. Local thickenings of the intima occur opposite the opening of a patent ductus arteriosus, both in the aorta and in the pulmonary artery, but it appears probable that the infective process begins at the pulmonary orifice of the ductus rather than at these thickened areas which in our case bore no vegetations.

3. Admixture of venous and arterial blood. The frequency of left-sided endocarditis and the immunity of the right side to infection has been attributed to the fact that arterial blood is the more favourable medium for bacterial growth. It is certainly true that dextral endocarditis is more common in those congenital lesions which allow arterial blood to reach the right side of the heart.

Summary.

It is evident that local thickening of the endocardium and increased local strain are factors in determining the onset of the infective process in congenital heart disease, but we suggest that the access of arterial blood to the right heart may explain the unusual frequence of dextral endocarditis in these cases.

In our opinion the preponderance of left-sided lesions in endocarditis in general cannot be adequately explained by the higher blood pressure in the systemic circulation, and we are impressed with the possibility that it may be due to the changed composition of the blood after passing through the lungs.

We are indebted to Dr. C. E. Lakin for his kindness in allowing us to publish the details of the case formerly under his care.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SOCIETY. The opening meeting of this society, at which Prof. J. S. Haldane, Oxford, is to read a paper on the Physiology of Acclimatisation to High Altitudes, has been postponed from Friday, Oct. 17th, till the following Wednesday, Oct. 22nd, at 8.15 P.M.

A PLEA FOR THE PRESERVATION OF THE PREMAXILLARY BONES IN CONGENITAL CLEFT PALATE.

BY ALBERT D. DAVIS, B.Sc., M.D. NEB., D.D.S.

(From the Department of Oral Surgery, University of Nebraska, College of Medicine.)

IT has been my good fortune to assist a noted oral surgeon in the compilation of data from all parts of the world on cleft palate and cleft lip. In going over the literature thus assembled, it seems to me that there is probably no other field of surgery in which there is such a variance of opinion as to the best time for operation, the objective aimed at, the technique to be employed, and the final results of operation. Most authors in this field seem to agree that the clefts of the lip should be closed, and some agree that clefts of the palate should be closed too. Others seem to be satisfied to approximate the hemispheres of the hard palate without effecting union. The more individual the operation and the easier its performance, the greater the tendency becomes to forget the primary objective where deformity exists—the restoration of normality as far as possible.

Brophy[1] gives the following current definition of cleft palate: "A congenital deformity, characterised by a fissure or fissures of the palate due to arrested development." In other words, congenital cleft palate is considered to be the result of incomplete development of the tissues necessary to enter into its normal formation. "The opinions of authors thus expressed," Brophy goes on to say, "have been based, no doubt, on their observation of the open space between the oral and nasal cavities. The error is easily explained, for the open space suggests an absence of tissue. But the deformity, the statements of many authors to the contrary notwithstanding, is *not* the result of *congenital deficiencies* of the parts in question, nor is it due to *arrested growth of the palate. All children who have congenital cleft palate, with rare exceptions, have in the palate at birth* the normal amount of tissue. The palatine plates, however, are frequently misplaced upwards, and the bones are not united in the middle line. The palate is *cleft*. Later in life it may atrophy for want of use. Therefore, a cleft palate is a fissure, a separation of well-developed parts, not (with rare exceptions) the result of arrested development nor failure of a normal quantity of tissue to enter into its structure." Most authors are now agreed that this is so, and, with this fact before us, it seems that the only logical course to pursue would be to preserve, as far as possible, all of this normal amount of tissue, assemble it into correct relationship, freshen its edges, unite and immobilise it until healing occurs. Nevertheless, some surgeons who agree with and support the definition itself do not follow this logical course. Either the definition is forgotten in the subsequent operative procedure advised, or it is totally disregarded.

There are many minor offences, but my object is to condemn the practice advised by certain authors relative to the disposition of the premaxillary bones in the more severe forms of cleft palate. In these cases the premaxillary bones are usually protruded for some distance anterior to the maxillæ, making a very ugly deformity. (Figs. 1 and 2.) Although these bones are protruded, and have the prolabium or central portion of the lip attached to them in front, it must be remembered that they form a part of the normal ununited tissue spoken of in the definition. Yet we find repeated instances in the literature where the author recommends that these bones be excised and the lip closed, in the expectation that the maxillæ will be moved more nearly together.

To anyone who has a well-grounded education in this special field of surgery, the excision of the pre maxillary bones in order to bring the lip over the maxillary bones is to be thought of in the same light as would be the amputation of a limb to heal a slight flesh wound. And yet, let me quote from a book published in 1919: "In severe cases the premaxillæ should be removed entirely, as the maxillæ then fall together and render the subsequent closure of the palatal cleft (which is usually present in these cases) an easier affair. The falling in of the lip which results from this course can be obviated by suitably designing the denture which carries the incisor teeth." The same authors advise "gouging out the teeth in the premaxillæ" if an attempt is made at its reposition and it does not fit well. They also state that "firm union of the bone rarely occurs."[2]

FIG. 1.

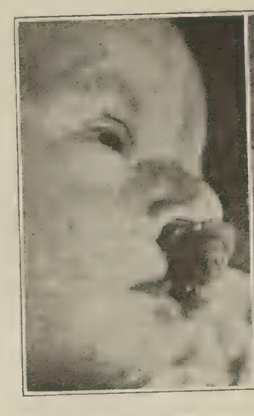

FIG. 2.

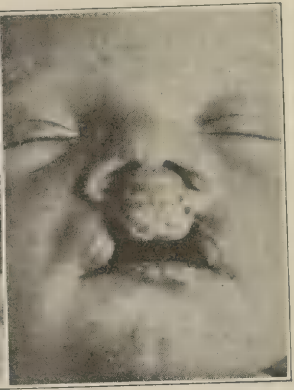

FIG. 1.—Tripartite cleft palate, showing protrusion of the premaxillary bones.

FIG. 2.—Front view of child with premaxillary bones protruded. Notice rounded elevations showing tooth buds in position.

An American author, an oral surgeon in one of the large eastern hospitals, says in his text-book: "In some cases of cleft palate, where the intermaxillary bone is turned up and attached to the septum of the nose in front, it is necessary to remove it altogether. In this case, the incisor teeth, both temporary and permanent, will be lost, as their germs are contained in these intermaxillary bones."[3] In Spain a book by Gaillard y Nogue, "Tratado de Estomalogia," shows in Figs. 150 to 152 inclusive, the treatment of double hare-lip. The premaxillæ have been removed, and during the closure of the lip the greater part of the prolabium is cut away, leaving an irreparable deformity.

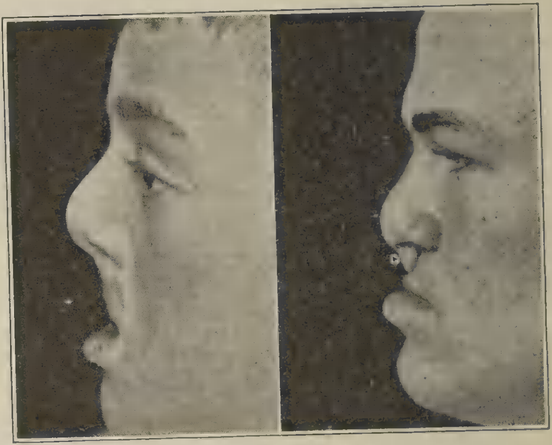
When a patient is brought with a congenital cleft palate, complicated with premaxillary protrusion and double cleft lip, it is the duty of the surgeon to correct the deformity, not to leave the parts beyond the stage of correction. In the days of Celsus, 42 B.C. to A.D. 37, the lip was closed over the deformity, no attention being given to the palate, so far as history records. Some surgeons of the present day have gone a few steps farther and trim away a section of the vomer, which allows the premaxillæ to be pushed backward and, without anchorage, freshened edges or immobilisation of these bones, suture the lip together, depending upon the traction of the orbicularis oris muscle to hold the bones in place until Nature heals the wound. A bony union cannot occur, and the bony cleft is only modified in extent—not closed. In cases of single clefts, the operation as originally designed by Celsus almost 2000 years ago is to-day advocated by many, with this exception, that they advise the closure of the cleft in the soft tissues at a later date, leaving the bones ununited.

When operations of this type are advised and taught to students by men of high standing in the profession, a plea for further enlightenment is necessary. Every obstetrician should be informed of the necessity of the proper procedure for these unfortunate children and should advise the parents to consult a specialist in this field.

When, as Brophy has stated,[1] there are innumerable failures due to improper operative procedures, it is time some definite stand should be taken to correct these appalling disasters. It is obvious to anyone truly informed in this work that, inasmuch as the premaxillary bones are a part of the normal arch and lip, their preservation should be of paramount importance. In constructing a normal lip a normal bony arch is essential. The premaxillæ, in these cases, form the most important part of the arch, as normal facial contour and expression are impossible without them. Not only is this true, but the premaxillæ contain tooth buds of usually two to four teeth which are important for the patient's future dentition.

The objective of the surgeon in these cases should be the correction of the deformity, and the restoration to normal as nearly as possible of all the displaced tissues. Ease in the accomplishment of succeeding operations and the virtues of artificial dentures are insufficient reasons for the excision of the premaxillæ. Lack of knowledge of their value to the patient and to the operator's ultimate success, in the light of surgery of the present day, is totally inexcusable. Upon the preservation of these protruding bones—unsightly as they appear, attached to the lower part of the nose like some neoplastic tissue—depends the formation of not only a normal bony arch, containing the teeth, but a normal lip and nose as well. If normality and correction of the deformity *are* the goal of the surgeon, excision of the premaxillæ renders this achievement impossible not only to himself but to any surgeon who may, unfortunately, follow him. (Figs. 3 and 4.)

FIG. 3. FIG. 4.



The results of excision of the premaxillary bones in infancy. After this mutilation normality can never be established.

Brophy[1] teaches that a bony cleft should be considered and treated as an ununited fracture. This is not a new procedure, but has been the foundation of his work for over 40 years. Fracture surgery teaches freshened edges, fixation, and immobilisation. If the surgeon will only visualise the cases of cleft palate with premaxillary protrusion as potential fracture cases with displacement and so treat them, then, and then only, will normality be established and the practice of excision of the premaxillæ be abolished.

Surgical authors who advocate the sacrifice of these important parts fail to comprehend the conditions of an ununited fracture and the treatment essential to its cure. Every properly educated and experienced surgeon knows that an ununited fracture cannot be cured without first exposing the fractured ends of the bone, denuding them of intervening soft parts, including the cicatricial and periosteal tissue, placing bleeding cancellated bone into contact with bleeding cancellated bone, correctly adjusting and immobilising them, and closing the soft parts over them so that perfect union and solidification will occur. Then the premaxillæ will be in their correct position and normality established. (Figs. 5 to 8.)

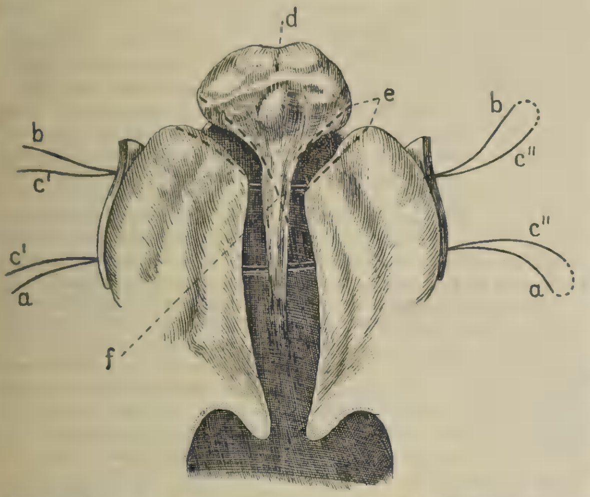
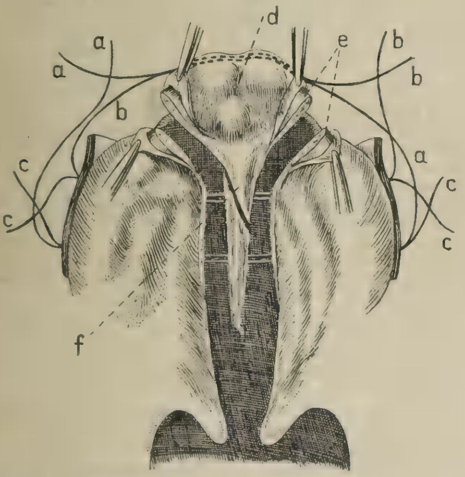
[3] Robert H. Ivy: Applied Anatomy and Oral Surgery.

FIG. 5.



Method of treating tripartite cleft palate. The wires have been introduced and the lead plates adjusted. The dotted lines indicate the incisions. It will be noticed that the vomer is cut obliquely so as to allow it to be moved backward into proper position. The wires, &c., are lettered in order that they may be identified in the subsequent figures. (Figs. 5–8 have been redrawn from Brophy.)

FIG. 6.



The second step in the procedure showing the flaps made in the muco-periosteum and the compact bone removed from the surfaces to be placed in contact. It will be noticed that wire sutures have been carried through the maxillæ and the vomer. These sutures will enable the surgeon to bring the bones into close proximity.

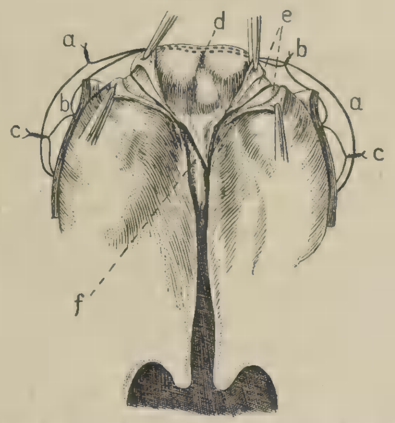
Conclusions.

1. The premaxillæ, even when protruded, are not abnormal nor excess tissue, but are normal tissue misplaced.

2. The function of the premaxillæ is to complete the normal, bony upper arch, support the lip and lower part of the nose, and give symmetry and normality to the face.

3. The author who recommends the excision of the premaxillæ must share equally with the surgeon who follows his method the blame for the permanent mutilation of the child.

FIG. 7.



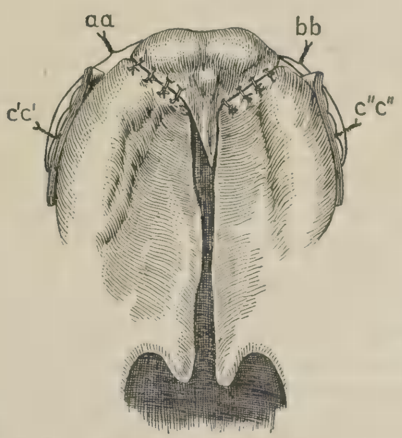
The flaps have been made in the membranes and the vomer is in correct position. The wires have been partially twisted. It will be noticed that the wire *a* is brought forward and passed beneath the muco-periosteum anterior to the premaxillary bones and twisted upon the right side. The wire *b* is carried forwards in the same manner and twisted upon the left side. The wire *c* is twisted against the lead plate so as to force the separated bones together. The *c* wires are twisted before the *a* and *b* wires.

4. Cases of cleft palate with premaxillary protrusion must be visualised as cases of potential fracture with displacement and modern methods of bone surgery employed to restore normality.

5. Excision of the premaxillæ destroys all hope for normality and produces permanent mutilation.

6. The obstetrician should be fully awake to the importance of consulting specialists in this field.

FIG. 8.



The premaxillary bones have been placed in their normal position and the flaps sutured with horse-hair. The mucous membrane over the vomer and edges of the hard palate have been split and the underlying bone freshened so that union takes place without placing any sutures in the median line. The soft palate is united later.

7. Ease in the accomplishment of succeeding operations and the virtues of artificial dentures are insufficient excuses for the excision of the premaxillæ.

8. Preservation of the premaxillæ, assembling the bones in their proper relationship, and immobilising them until union occurs are necessary if normality is ever to be obtained.

Clinical and Laboratory Notes.

A CASE OF IRON-STONE PHTHISIS.

By Sir Kenneth Goadby, K.B.E., M.R.C.S. Eng., D.P.H. Camb.,

MEDICAL REFEREE FOR INDUSTRIAL POISONING.

The following case of phthisis in an iron-stone worker is of interest in its bearing on the action of dust as a lung irritant predisposing to secondary tuberculous infection.

A. B., iron-stone miner employed in winning hepatite iron ore. He was engaged in the use of compressed air apparatus, by means of which holes are driven into the rock for the insertion of blasting material.

He joined an approved society in July, 1912, with no history of disease. In May, 1918, he was certified as suffering from influenza; recovered at the end of 20 days. On Dec. 13th, 1923, he was treated for chest complaint, became progressively worse, and died on Feb. 17th, 1924.

Radiographic Examination.—In May, 1919, he was examined radiographically along with 11 other cases of iron-stone miners by Mr. C. Thurstan Holland, who reported:—

"Screen examination: Diaphragm moved equally and well both sides; no definite abnormality detected. Has worked for three years on a drilling machine. Radiographic plate: Linear shadowing along the bronchi is exaggerated; there are numerous rather large, opaque spots present, especially well-marked along the linear shadows extending from the right root of the lung. Smaller spots are evident along the same lines in the left lung."

Death Certificate.—"Death from pulmonary tuberculosis 1½ months in duration, verified by post mortem."

Lung Examination.—The right lung only was sent for examination. When placed in water the upper lobe sank, but the middle and lower lobes floated. The upper lobe showed numerous large, white, bulging areas; was generally consolidated and hard to the touch. There were numerous old adhesions and evidence of recent and old pleurisy. There had evidently been some cardiac adhesions in addition. On incising one of the white swellings a large amount of brown, thick, purulent material escaped. Films made from the pus showed numbers of tubercle bacilli, pus cells, polymorphonuclear and mononuclear cells on staining by Giemsa. Gram stain showed large numbers of diplococci, Gram-positive, many capsulated. Another portion of the lung was excised under aseptic precautions and cultivations made therefrom. Pneumococci were isolated. Portions of the upper and lower lobe were examined histologically, stained, (1) hematoxylin eosin, (2) Van Gieson, (3) Gram-Weigert, (4) potassium ferrocyanide.

Microscopical Examinations of the Sections showed a generalised consolidation, complete blocking of the majority of the bronchioles; the alveolar tissues almost entirely replaced by fibrous tissue. A large amount of dust is situated in the immediate vicinity of the blocked bronchi and throughout the consolidated tissue. The arrangement of the fibrous tissue is loose, and does not show the same nodular formation that is present in cases of advanced silicosis, the fibrosis being of a more generalised and irregular type. The specimens stained with potassium ferrocyanide, both in macroscopic and microscopic sections, showed a large amount of diffuse blue staining. In the macroscopic specimen the blue staining follows the lines of new fibrous tissue formation, in some cases being parallel to the smaller bronchioles, showing that the iron had diffused into the tissues. The microscopic sections showed intense iron staining, particularly around the occluded bronchioles, but also diffusely through the fibrous tissue. With the polariscope a certain number of brightly refracting crystalline bodies were found scattered about in the fibrous tissue, but on comparison with a case of silicosis these refractile bodies are much smaller in number. On the other hand, even a normal lung will show a few of these bodies.

Considerable interest attaches to this case. (1) The development of phthisis appears to have been predisposed to by the irritative condition of the lung; (2) the dust inhaled was largely a compound of iron, but the analysis of dust from the mine gives the presence of small quantities of quartz.

In silicosis of the lung occurring in ganister workers and gold miners there is no question that the inhaled silica particles act as an irritant, setting up chronic fibrotic changes, the tissue being secondarily infected with the tubercle bacillus giving rise to phthisis. At one time the angularity of the particles breathed was supposed to determine the fibrous tissue production, but latterly, from the researches of Gye and Kettle[1] and Kettle,[2] it seems probable that the silica undergoes solution and acts as a tissue poison. Haldane[3] considers that the irritative action of inhaled dusts depends on their solubility, or that they contain occluded substances—e.g., coal dust—that the soluble or occluded substances produce a physiological reaction and the particles are got rid of, and it is only the particles which are physiologically inert that give rise to inflammatory changes leading to susceptibility to tuberculous infection. In the present case the amount of silica would be small, but the amount of iron-stone dust of a soluble nature exceedingly large, and that this actually became dissolved and permeated the tissues is shown by the iron staining of the specimens. It would seem therefore possible that the iron carbonate and oxide had a specific irritative action because of its solubility rather than its inertness.

It is somewhat significant that X ray photographs taken in 1919 show extraordinary similarity to cases of early silicosis as observed in the Rand mines in South Africa and the Broken Hill mines in Australia.

Whatever point of view we may take, it can hardly be doubted that the presence of large quantities of iron in the lung had an injurious effect in this case; on the other hand, there is no record of the other ten iron-stone miners who were photographed at the same time as this case having succumbed to tuberculosis, and no general conclusions can be therefore drawn that inhalation of iron-stone dust is a common cause of tuberculosis of the lung in iron-stone miners.

AN UNUSUAL FORM OF LEFT INGUINAL HERNIA.

By John A. C. Macewen, M.B., C.M. Glasg.,

SURGEON, GLASGOW ROYAL INFIRMARY; CLINICAL LECTURER, UNIVERSITY OF GLASGOW.

The following case presents several points of interest which justify its being placed on record.

The patient, a man of 27, was admitted to the Royal Infirmary, Glasgow, complaining of attacks of pain which radiated from the left inguinal region across the lower abdomen. He stated that he had a hernia in infancy, which was easily reduced, and was treated by skein of wool, and later by a truss. The hernia disappeared, and did not return until the age of 19, when he was for the first time engaged in heavy work in a munition factory. At this time the hernia was about the size of an egg, generally disappeared when he lay down, and sometimes remained away for weeks at a time. He again began to wear a truss, and had no difficulty until one morning, shortly before admission, when the swelling appeared just as he was about to put on the truss. On this occasion there was great pain, and the hernia was reduced with difficulty. The hernia had not returned since, but he had frequent attacks of pain.

On examination no swelling was visible or palpable. The cord was possibly slightly thicker than normal, but the external ring was not enlarged, and there was no impulse on coughing. Patient, however, said that the pain he suffered at times was so severe that he desired operation.

Operation was accordingly performed, and a congenital sac was found, containing two appendices epiploicæ. These appendices were attached to the large intestine by long narrow stalks, which passed through an extremely narrow opening at the upper end of the sac. The aperture was just sufficiently wide to permit of the passage of the stalks without strangulation, and thus the appendices were retained in the sac and dragged upon the large intestine which lay in the abdominal cavity close to the narrow aperture in the sac. The radical cure was performed and patient made an uninterrupted recovery.

The case is interesting, apart from the pathological aspect, in respect of the impossibility of diagnosing the condition before operation, and the readiness with which a suspicion of malingering might have arisen had there been a question of compensation.

I am indebted to Miss H. L. Paterson, my junior house surgeon, for the preparation of notes on the history of the case.

Reviews and Notices of Books.

SOCIAL INSURANCE, WHAT IT IS AND WHAT IT MIGHT BE.

By ALBAN GORDON, B.Sc., F.C.S. London: Fabian Society and George Allen and Unwin, Ltd. 1924. Pp. 150. 6*s*.

THIS excellent exposition of the whole subject of social insurance is timely, because the differences of view between the medical profession and the approved societies in respect of the working of the National Insurance Acts are coming almost immediately under the scrutiny of a Royal Commission: in a still better sense it is timely, for it is an earnest attempt to look far ahead, and foresight at any date is opportune. All political parties have placed social insurance in the forefront of their programmes, but the promises have carried little conviction, for many of the politicians have not grasped the principles which must underlie all schemes, so that they have been unable to explain either why they think certain developments desirable, or how they propose to mould affairs in the future. Mr. Gordon's book should be instructive to those who are called upon to take active leadership, and should also inform the public upon those essential facts whose comprehension is necessary if legislative proposals are to be criticised with intelligence, and either helped to fruition or relegated to obscurity in accordance with their merits.

The book is divided into two parts, of which the first sets out the subjects appropriate for insurance, analysing the treatment which they receive at the present; while the second consists of a scheme for the unification of social insurance, where the necessity, indicated in the first part, is assumed for the coördinating and supplementing of existing diverse systems. The need for a national scheme of health insurance is not discussed, and indeed it has been abundantly proved, but so has the justice of some of the complaints against the working of the methods as we now know them; for no one can deny the inadequacy of the benefits provided by the National Insurance Act, the overlapping of the thousands (literally) of separate bodies involved, the neglect of preventive measures in disease, and the lack of personal touch in administration. The grounds for these complaints are set out here, and analysed, with the inference that the working of the approved societies, viewed from the broad national aspect of the prevention and cure of sickness, is proving a failure. Full credit is given to the societies for bringing the Act into operation, and for arduous and anxious labour in carrying-on through the first 11 years of national insurance, and it is suggested that many of the failures and anomalies would have been avoided had the original qualification for an approved society remained a membership of 5000 at least, the multiplicity of small societies having hopelessly damaged the scheme. And at this point in the book a short but revolutionary proposal, as a solution of the main obstacle to efficient action and development, is put forward succinctly. In Mr. Gordon's words, "A simple and efficacious solution lies ready to hand—remove medical benefit from the Insurance Act altogether," because the prevention of the incidence of illness and its prompt treatment upon recognition do not form a logical section of any organisation taking charge of sickness benefit and disablement benefit; for these are self-contained cash affairs, can depend on an actuarial basis, and can be restricted to persons paying contributions—none of which holds good for what is implied by medical benefit. Perhaps if the insurance committees, specially created for the purpose of administering medical benefit in every county and county borough, had worked in accordance with the original designs of the Act, and had taken a large share in the handling of local sanitary affairs, the position that we are now in would have been less critical, but while these committees confine their activities to the disbursing of monies and the scrutiny of prescriptions, the cost at which the country is for their maintenance seems inexcusable. While the insurance committees function only in such a manner medical benefit remains much as it was before the Act—that is to say, it has become the rendering of service by individual practitioners to their insured patients, for these extremely busy men with little machinery by which to obtain the services of specialists or the accommodation of institutional treatment for their charges, cannot deal both with the mass of existing disease and be responsible for the early diagnosis of such maladies as, for example, tuberculosis and venereal disease. Moreover, medical benefit as at present devised has been only directed to a limited section of the working class, and the position of the average middle-class household remains unaffected by the Act, though this class is quite unable to afford such a draft upon its resources as is implied by a major operation or a lingering illness.

The scheme to meet the circumstances, which forms the second part of the book, is a brave attempt to look ahead, based upon a supposition that the need for profound alteration in our system of social insurance is proved; it is put forward tentatively as *a* way, and not as the *only* way of dealing with what is termed "the slimy mess of the Poor-law" and the curse of unemployment. The basis of this comprehensive scheme for national social assurance assumes that the risks of sickness, unemployment, accident, widowhood and orphanhood, indigent old age, and premature death can be provided for by insurance, and can all be administered in one comprehensive scheme, a State national minimum of insurance being insisted on as a corollary to wage minimums and as supplementary to measures for the prevention of destitution. Such compulsory insurance is based in the scheme upon local territorial units, and graded with relation to maintenance of a reasonable standard of existence, while the scheme throughout provides for the prevention of the risks which it proposes to compensate. The contributions from employer and employed, forming the gross income, are to be subsidised, it is proposed, not only from the Central Exchequer, but from the local rates, the last sums implying merely a diversion of the existing Poor-law rate. The insurable matters being thus provided for, schemes for medical benefit—i.e., for the public health of the country—would fall into their logical place to be administered by the public health authorities, full coöperation being insured between the medical practitioner and the State officials, medical and lay.

This is an excellent little book.

CLINICAL STUDIES IN EPILEPSY.

By DONALD FRASER, M.D., F.R.F.P. & S. Glasg., Consulting Physician, Royal Alexandra Infirmary, Paisley. Edinburgh: E. and S. Livingstone. 1924. Pp. 240. 7*s*. 6*d*.

THERE is no disease of which the causation is more obscure than epilepsy. The object of Dr. Fraser's book is to bring together reports of a number of cases of different varieties of the disease in the hope that from their discussion some hint of the pathogenesis of epilepsy may emerge. His arguments are based on the work of Hughlings Jackson, and he quotes Jackson's words again and again with implicit confidence. This attitude of reliance on a great teacher has led, however, to a fault in the book—a lack of precision in the author's own views on the nervous mechanisms at work in epileptic manifestations. In one of the citations (p. 21) there occurs the phrase, "epilepsies in the scientific sense—that is, they depend on discharges beginning in some part or parts of the cortex cerebri," and later on (p. 67) Dr. Fraser's comment, "This hypothesis of a discharging lesion is a very convenient one, though what takes place in the highest levels is, we believe, not a discharge of energy alone but a deprivation of it, leading to uncontrolled discharge from lower and subordinate centres." But surely this distinction is vital, for on it depends whether we regard epilepsy as the result of irritation or of inhibition of the highest centres, and our views of causation will vary accordingly. The hypothesis which looks upon the epileptic attack as a release phenomenon, consequent upon an inhibition of the highest centres, is the one which is the most satisfactory, and although various chapters of this book are imbued with it, it is a pity that it is not stated with more insistence. The hypothesis is applicable to all the psychic and motor disturbances—aphasia, amnesia, fugues, loss of consciousness, mania, convulsions, and twitchings—described in the interesting case-reports; it may be applied also to the negative sensory phenomena—e.g., temporary scotomata—and its application to the positive sensory disturbances, though less easy, is not impossible. Vaso-constriction, if the possibility of its occurrence in the cerebral vessels be granted, affords a satisfactory cause of cortical inhibition, and it is this theory that the author supports; he argues strongly in its favour, and sees its causal agent in some toxin allied to histamine. The chapter devoted to the effects of "the cerebro-spinal reflex" is less convincing. The main interest of the book lies, and is meant to lie, in the case-reports, and here is food for much thought.

Dr. Fraser reproaches British neurologists with the fact that the writings of Hughlings Jackson have never been published collectively, and it may be hoped that at least a representative selection of his papers will be brought together before long.

PATHOLOGICAL TECHNIQUE.

Eighth edition. By Frank Burr Mallory, A.M., M.D., Pathologist to the Boston City Hospital; and James Homer Wright, A.M., M.D., S.D., Pathologist to the Massachusetts General Hospital; Assistant Professor of Pathology, Harvard Medical School. London and Philadelphia: W. B. Saunders Company. 1924. Pp. 666. 32*s.* 6*d.*

This work has long ago established itself as a popular and reliable manual of pathological technique. For this, the eighth, edition several sections have been added or rewritten by various collaborators, and the whole book has been thoroughly revised. While the general level of the different sections is high, some, notably that dealing with histology, are outstanding. Should any omissions be considered advisable in future editions, the pages dealing with animal inoculations might well be sacrificed. In its present form this chapter is a poor substitute for practical demonstrations, and is not up to the standard of the rest of the book. We can recommend this volume as one which few laboratory workers can afford to ignore.

MODERN METHODS OF TREATMENT.

By Logan Clendening, M.D., Assistant Professor of Medicine and Lecturer in Therapeutics, Medical Department of the University of Kansas. London: Henry Kimpton. 1924. Pp. 691. 45*s.*

We welcome this book as a rational and straightforward exposition of the present-day outlook on treatment. Singular skill is shown in the apportionment of its true value to each of the methods at our command. It is remarkably free from that type of traditional treatment which is often described but seldom used; on the other hand, it is no less free from the over-enthusiasm of the specialist. Further, the rationale of treatment is well explained on a physiological basis. The section on drugs contains unusually little dross. The first half of the book, consisting of 440 odd pages, is on the "Methods used in Treatment," of which space 140 pages are devoted to drugs. Dietetics, in the same part of the book, fills nearly one hundred pages and gives thoroughly practical hints. The various methods of treatment described in the rest of this section of the volume, such as the production of artificial pneumothorax, transfusion of blood, gastric lavage, are given with sufficient detail to make them of definite value to the man who is called upon to carry them out. In the second portion of the book, entitled the "Application of Therapeutics to Particular Diseases," the facts mentioned in the earlier portion are collected and applied. The diagrams are well chosen, many of them being pictorial descriptions of the stages of the processes used. The pictures of Sippy's[1] method of treatment for gastric ulcer will fix it in the memory in a way which no written account or table of figures could achieve. Agglutination, as shown in another series of pictures, becomes a simple phenomenon to understand. Prof. Clendening's reason for giving no section on antipyretics is interesting—"because the treatment of fever, per se, is a relic of some other age of treatment." But is he right, or at any rate in accord with modern notions, when he says that "fever is the reaction, probably *defensive*, of the body to infection"? We should not, it is true, rashly interfere with a raised temperature, but fever is now generally believed to throw a strain on rather than to defend the bodily mechanism. The book contains a sufficient amount of episode and history to make it pleasant reading. There is a slip in connexion with Thomas Dover, who is said to have recommended his powder in 1762. Dover died in 1742. Generally, this volume deserves high praise; it is so well balanced that it is suitable both as a text-book and as a work of reference, a standing to which few books attain.

AIDS TO PSYCHIATRY.

By W. S. Dawson, M.D. Oxf., M.R.C.P. Lond., D.P.M., Senior Assistant Medical Officer, Maudsley Hospital. London: Baillière, Tindall and Cox. 1924. Pp. 309. 4*s.* 6*d.*

In the "Aids" series any approach to uniformity of size must mean that specialised subjects will receive fuller treatment than can be afforded to "medicine" and "surgery" in the volumes with corresponding titles. In this consideration lies the only adverse criticism which this volume is likely to receive. It is, in fact, a text-book differing little in size and scope from several well-known works on the same subject: the difference in bulk is counter-balanced by the use of small type and comparatively thin paper. The student who supposes that he need learn the whole contents of this volume for his qualifying examination will, no doubt, be erring on the right side, and the mistake will stand him in good stead in the future.

The arrangement is on orthodox lines, with a commendably simple classification of varieties of insanity: indeed, a warning is needed that in practice cases cannot easily be relegated to any of these simple categories, and sometimes not at all. There is an excellent chapter on treatment, a full discussion on all the important legal bearings of mental disorder, and a particularly complete chapter on mental deficiency, in which a simplified series of tests of mental age is given—a feature of the utmost practical value. Psycho-analysis is treated with due impartiality, and there is a valuable section on the Theories of the Neuroses (one would rather have said "Hypotheses"). At its extremely moderate price this book is likely to achieve great popularity.

L'ALIMENTATION NATURELLE CHEZ L'ENFANT.

By Dr. Monteuuis. With a Preface by Prof Nobécourt. Paris: A. Maloine. 1923. Pp. 278 Fr.8.

This posthumous work of the late Dr. Monteuui conveys an appeal to French mothers to eschew methods of feeding based on caloric requirement and to return to the older habits of diet consistin of more natural and less "industrialised" foodstuff The author's principal contention is that the *qualitative* value of the various cereals is the importan factor, and that this varies according to their mode of preparation; white bread is regarded as a national peril. The work consists largely of recipes, and should provide an extremely varied dietary for children.

---

[1] The death of Prof. B. W. Sippy was announced o August 15th at Chicago in his fifty-eighth year. He had bee since 1906 professor of medicine in the Rush Medical College.

INFECTION AND RESISTANCE.

Third edition. By HANS ZINSSER, M.D., Professor of Bacteriology and Immunity, Harvard University, &c. New York: The Macmillan Company. Pp. 666. 24*s*.

THE literature on immunity has reached such enormous dimensions that it may be doubted whether any one man is fully conversant with it. Only by exceptional industry is it possible to cope with the flood of modern publications on the subject, and a trained and critical intelligence is needed to divide the wheat from the chaff and to estimate the true value of recorded observations. Under these circumstances a small dogmatic text-book on immunity becomes almost an impossibility, while a more ambitious work may defeat its ends by leaving the student in a state of hopeless bewilderment. Dr. Zinsser follows a middle course with skill and success. His book contains a mine of information, which is developed clearly and logically and with commendable fairness and moderation. Opposing points of view are faithfully recorded, and though the author's personal opinions are never in any doubt, the student is placed in the position to form his own conclusions. For this edition the work has been revised and partly rewritten, and it may be thoroughly recommended as a trustworthy guide to a difficult subject.

INSTRUMENTS AND APPLIANCES FOR OPERATIONS.

Second edition. By Lieut.-Colonel CASTOR. Revised by Lieut.-Colonel CONNOR, I.M.S. Calcutta: Thacker, Spink and Co. 1924. Pp. 34. 1*s*. 6*d*.

THIS little pamphlet describes the requirements for a satisfactory small operating theatre, whether improvised or permanent, and the essential outfit. Lists of the instruments required for various common operations follow, with a few notes as to dressings and the position of the patient during operation. It is all very good and to the point. We would only offer one criticism—there is not really any such organ as the Æsophagus, nor was there even when Æsop anticipated the present authors by also advising the use of a pair of long-bladed forceps in a case of severe dysphagia.

The book is well arranged, and would be of real use to anyone who has to select instruments for operations.

HIPPOCRATES.

Hippocrates and His Successors in Relation to the Philosophy of Their Time. Being the FitzPatrick Lectures for 1921–1922. By R. O. MOON, M.D. Oxf., F.R.C.P. London: Longmans, Green and Co. Pp. 171. 6*s*.

DR. MOON'S admirable lectures should be read in conjunction with the Translation of Hippocrates now appearing in the Loeb Classical Library. The two first lectures deal with Hippocrates in relation to the philosophy of his time and give an excellent account of the various systems of philosophy which affected his opinions—both those schools, such as that of Pythagoras, which existed in pre-Hippocratic times, and those, such as that of Democritus, which were contemporaries of Hippocrates. The last two lectures deal with post-Hippocratic schools of medicine and philosophy. With regard to Pythagoras, Dr. Moon points out that the Greek idea of the soul being a Harmony "seems to have originated from Pythagoras in connexion with Medicine," and he goes on to quote from Plato's Phædo a remark of Simmias the Pythagorean, in which he argues that our soul is a kind of temperament and attunement of the warm and the cold, the moist and the dry, when they are mingled with one another well and in due proportion. Dr. Moon further quotes from "Greek Philosophy" by J. Burnet, who says that "Health means just being in tune, and disease arises from undue tension and relaxation of the strings; even now we speak of tonics in medicine as well as in music." We might remark in this connexion that in the Greek musical scale the tonic was not as we call it, the beginning and the final of the scale, but the middle note of it, and they called it μέση. The intense Greek feeling for the *mean* in everything may have been the reason why they placed their tonic in the middle.

JOURNALS.

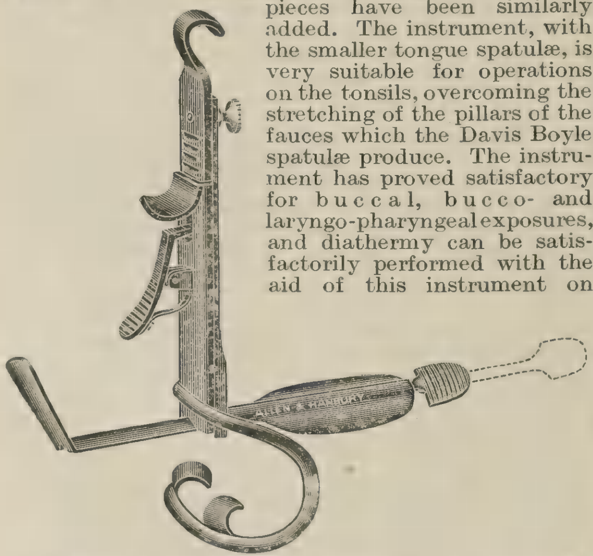
BRITISH JOURNAL OF OPHTHALMOLOGY. September, 1924.—M. L. Hepburn: Classification of Diseases of the Choroid. The writer points out the classification of inflammatory diseases of the choroid alone under 26 different headings, as is done in the American "Encyclopædia of Ophthalmology," is totally unjustifiable. Mr. Hepburn's own classification is under five heads: (1) Inflammatory, (2) vascular, (3) degenerative, (4) congenital, and (5) new growths. The paper is all too short—we could do with more examples, and especially with illustrations of each class. Some controversial matter is included—viz., the inclusion of retinitis pigmentosa as a choroidal disease of vascular origin and the objection to treating macular affections as a class by themselves.—W. G. Laws describes a rare form of retino-choroiditis, possibly associated with pituitary dysfunction. Four cases are cited in which this association occurred. They were characterised by an acute onset with much inflammatory change in the optic nerve head and retina, widespread but always superficial and therefore possibly secondary lesions of the choroid, a self-limited course, and recovery with relatively good vision.—C. L. Preziosi discusses the electro-cautery in the treatment of glaucoma. This paper advocates the use of the electro-cautery in lieu of the trephine in performing a sclerectomy for glaucoma. The chief advantages claimed are: (1) simplicity of technique; (2) impossibility of injuring deep structures; and (3) the slowness with which the anterior chamber is emptied, reducing the risk of hæmorrhage. Iridectomy is not performed, which the writer claims is an advantage, but which may be the opposite.—E. R. Chambers, of Bristol, gives the notes of a case of paralysis of divergence in encephalitis lethargica. In connexion with the recent epidemic he has seen six similar cases within a few weeks. There has been a difference of opinion as to the existence of this condition. Sir George Berry, we note, holds that all these cases are really instances of spasm of convergence and that the so-called centre for divergence in the brain does not exist (cf. Trans. Ophth. Soc., 1901, p. 268).

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.—The first paper in the Journal for August was delivered by Lieut.-Colonel J. A. Anderson before the War Section of the Royal Society of Medicine in April. He explains the new motive of the sanitary specialist in the army, concerned rather with health and its promotion than with disease and its prevention. He considers that there was too much thought in old days of infectious diseases and their prevention to the exclusion of all else; but was it not the work of the pioneers in this field that nearly extinguished typhoid and undulant fevers, and, by reducing illness, left officers with fewer cases to treat, and thus has given them time now to spend on diminishing the lesser ailments of the men?—The first part of Captain J. S. K. Boyd's Parkes' Memorial Prize Essay on the Prophylaxis of Malaria appears in this number. It promises to be a clear and well-balanced account of the problem.—Major C. M. Finny reports the case of a soldier in the Gordon Highlanders, who, running in an inter-regimental cross-country race, twisted his left foot inwards three miles from home, and, as he stumbled, twisted the other ankle. However, he picked himself up and continued to run, finishing twelfth out of a large field. He complained next morning, and "the X ray showed a transverse fracture of both fibulæ two inches from their lower extremities with slight comminution." Treatment consisted in rest and splints for a week, with daily massage, then active movements, and walking was allowed 12 days after the accident.—Colonel J. A. Hartigan tells of a trip he made from Jamaica to Panama to see the wonderful canal. In the days before Gorgas, between 1882 and 1889, he tells us there were 5000 deaths in the Ancon Hospital, 1200 from yellow fever. A devoted official, an amateur gardener, to protect her garden from ants, arranged a shallow wet gutter all round it. In this "the yellow fever mosquito bred, and so the unfortunate patients became infected." The Governor of the Canal Zone is a regular officer of the U.S. Engineers, and the chief health officer, similarly, always comes from the U.S. Army Medical Corps. The other officials are mainly civilians. All water supplied to ships is filtered and "disinfected" (probably chlorinated). What luxury for those who live in ships! The admission-rate for malaria among employees during 1922 was 17 per 1000, but in 1905 it was 514. Great attention to detail marks all the sanitary work in the Zone.

New Inventions.

A MODIFICATION OF DAVIS BOYLE GAG.

THE points in connexion with this instrument are: the ordinary straight tongue spatulæ have been made to fit the Davis Boyle gag, and the epiglottic extension pieces have been similarly added. The instrument, with the smaller tongue spatulæ, is very suitable for operations on the tonsils, overcoming the stretching of the pillars of the fauces which the Davis Boyle spatulæ produce. The instrument has proved satisfactory for buccal, bucco- and laryngo-pharyngeal exposures, and diathermy can be satisfactorily performed with the aid of this instrument on growths in any of the above-mentioned regions. By firm traction, in an arc, on the handle piece and with the assistance of the epiglottic extension piece, a good view of the larynx can be obtained. The instrument is intended to replace in a large measure the cumbersome suspension apparatus, and will be found to meet the case in most of the instances where the latter is usually employed. With this instrument, as with the suspension apparatus, one cannot expect successfully to cope with those cases who have short, thick necks. The instrument is considerably cheaper and of smaller bulk, and is satisfactory for most cases. A point worth mentioning is that the surfaces of the parts are dull black, which fact is of great assistance in that reflections are practically abolished.



Messrs. Allen and Hanburys, 48, Wigmore-street, London, W., are the makers.

Brisbane. R. GRAHAM BROWN, M.R.C.S. Eng.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the statistics of six health resorts. The low birth-rates and high death-rates from all causes and cancer are striking, and accounted for by the large proportion of retired people and invalids who seek out a pleasant climate in which to end their days, and, as a corollary, by the larger proportion of females engaged in domestic service and the smaller proportion of children.

Name of town.	Estimated (R.G.) population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Bournemouth	82,200	13·0	13·6	1·1	1·7	1·6	26	60	2·8
Hove	44,340	11·0	14·0	1·1	2·4	1·9	22	51	4·1
Scarborough..	37,970	17·1	13·8	1·0	2·0	2·3	36	68	3·0
Torquay ..	34,100	14·3	15·1	1·2	1·9	2·2	29	49	2·0
Leamington ..	28,790	16·2	13·5	0·9	1·6	2·1	34	57	4·3
Lytham St. Annes	20,910	11·5	12·4	0·5	2·1	1·5	17	46	0·0

Bournemouth.

Dr. A. D. Edwards gives his own estimate of the population as 95,600, or 13,400 in excess of that of the Registrar-General. The report includes some interesting particulars with regard to the corporation housing scheme. This scheme at present includes 164 houses, all of which contain at least three bedrooms as well as a parlour and bathroom. The rents (inclusive except for the water-rate) are as follows:—

Eighty-eight B type in pairs, 12*s.* 6*d.* per week.
Six four-bedroomed houses in pairs, 14*s.* per week.
Sixty B type in blocks of four, 12*s.* 6*d.* per week.
Four single four-bedroomed houses, 15*s.* 6*d.* per week.
Three single B type, 14*s.* per week.

Evidently the four-bedroomed houses were found to be too big, as four out of ten have been adapted so as to accommodate two families, the tenant of each half being responsible to the corporation for half of the rental. On receipt of a written application the Housing Committee may grant permission to sublet to another family provided that the subtenancy includes a sitting-room, a bedroom with a fireplace, and the joint use of scullery, bathroom, and w.c. The subtenant's rental must not exceed half the rental and water-rate, and is paid direct to the superior tenant. At the end of December, 1923, 51 (or nearly one-third) of the 164 houses had subtenants. At the same date 75 of the tenants had received permission to have poultry runs. The number of poultry kept must not at any time exceed eight, and the height of the poultry shed must not exceed 5 feet. The permission to erect cycle sheds is granted subject to conditions imposed by the Buildings Committee. At the present time there are 21 such sheds.

Hove.

Dr. Augustine Griffith points out that the unnotified cases of pulmonary tuberculosis are usually visitors who have recently come to the town in an advanced state of the disease. In order to secure disinfection of lodgings occupied by consumptives a circular letter was sent to all medical practitioners asking them to notify the medical officer of health of changes of address of tuberculous patients. Dr. Griffith thinks risk and annoyance would also be avoided if house agents inserted a clause in their agreements to secure the disinfection of a house after occupation by anyone suffering from consumption. Dr. Griffith draws attention to the great change in the age and sex constitution of Hove since the beginning of this century. In 1901 the death-rate of Hove needed no correction in order to compare it with England and Wales, whereas now, in order to make a proper comparison, the death-rate requires to be multiplied by the factor 0·761. Between 1911 and 1921 the population under 5 years fell by 9 per cent., that between 5 and 35 increased by less than 10 per cent., while the population over 65 years of age increased 44 per cent. When the correcting factor is used the death-rate of Hove in 1923 is reduced from 13·96 to 10·62.

Scarborough.

Dr. S. F. Linton, in commenting on the high death-rate from cancer, draws attention to the unusually large proportion of female and aged residents. Scarborough has not yet got rid of its privy middens. Of a total of 10,099 houses, 1251 are supplied by privies, in addition to those which have privies as well as w.c.'s. The presence, particularly in the poorer parts of the town, of this large number of privies is a really great danger to the health of the people, says Dr. Linton, and any effort would be worth while to secure their abolition during the next three years. In 1919 an estimate was put forward that 350 houses were needed immediately, in addition to 632 houses for the accommodation of persons displaced by the clearance of unhealthy areas. So far only 95 houses have been provided. Requests are constantly made for permission to occupy houses which have been condemned and closed, and Dr. Linton states that there can be no question as to the harmful effects upon the public health caused by the housing conditions which prevail in the older parts of the town. The total hours of sunshine in Scarborough during 1923 were 1411·1, which is to be compared with an average of 1463·3 for the last 35 years.

Torquay.

Dr. Thomas Dunlop gives a glowing account of the corporation medical, electrical, and Turkish baths, which have been recently reconstructed. The water-supply of Torquay in times of continued drought has given some anxiety in the past. This difficulty is now to be overcome by the laying of a duplicate 14-inch main from Newton Abbot to Great Hill, where a service reservoir will be constructed to contain 1½ million gallons. The new reservoir will not only supplement the supply given by the town service reservoirs but will also supply water to houses at the highest levels. The water is a soft upland surface water which is subjected to mechanical filtration to remove peaty matter, and contains naturally enough lime and magnesia to prevent any plumbo-solvent action. The Torquay Corporation obtained last year a local Act which gives them many useful powers, including provisions for the protection of the food-supply. Persons dealing in shell-fish are required to furnish the source of their supply. The inspectors of the corporation are authorised to inspect carcasses intended for sale in the borough in slaughter-houses within a radius of six miles of the borough. This provision should be very useful when a public abattoir is erected as recommended by Dr. Dunlop and as provided for in the new Act. An effort was made to obtain a clause to enable the corporation to deal speedily with housing defects by their inclusion as nuisances within the meaning of Section 91 of the Public Health Act of 1875, but, to Dr. Dunlop's regret, this clause had to be dropped owing to the opposition of the Ministry of Health.

Dr. Dunlop records his opinion that the sanitary authority which administers the maternity and child welfare scheme should also be the supervising authority for the purposes of the Midwives Acts. He also points out that some of the "bona fide" midwives have ceased to be on the midwives' roll, and now act as so-called maternity nurses, but really as midwives without being subject to any supervision, and that they are encouraged to do so by various medical men. Only 11 expectant mothers attended the centre for antenatal advice, the number of births being 503.

The number of fish and chip shops is growing, and there were six new premises licensed during the year. All the newly established businesses have up-to-date apparatus, but, in spite of that, Dr. Dunlop thinks that in future applicants for licences should produce evidence that the occupiers or owners in the neighbourhood are favourable to the establishment of the new business. The 48 new municipal houses on the West Hill estate, sanctioned by the Ministry, have been completed and occupied. In order to encourage private enterprise the council have sold all the available building sites on the West Hill estate at an average of £50 per site. This scheme is only likely to benefit those who can build houses for themselves, and Dr. Dunlop thinks there is a "very arid prospect" for those who are only able to rent. One builder agreed to build 36 houses for renting, but owing to labour difficulties he has now decided to build only 12. The 76 houses completed during 1923 were mostly detached villas and bungalows, and their erection has had no appreciable effect on overcrowding or in enabling the corporation to close unfit houses. The corporation are endeavouring to deal with the Pimlico insanitary area, but have as a preliminary to erect 50 houses for the accommodation of the dishoused occupiers of the area. Notwithstanding the many difficulties much has been done in the way of housing repairs.

Leamington Spa.

Dr. W. L. Goldie gives an account of a small epidemic of paratyphoid fever. The usual sources of possible infection were investigated with negative results. Towards the end of August suspicion was directed towards a confectionery business. Over 80 per cent. of the cases notified had had food from this establishment. The employer gave every assistance, and ultimately an employee was found whose blood gave a positive reaction to the *Bacillus paratyphosus* B, the particular organism found in all the cases. This employee was the packer at the central establishment and the only person who handled the food that was sent to the different shops under the same management. She ceased work on Sept. 5th, and no further cases were reported after Oct. 6th, a time which would cover the incubation period of the disease and the period of the illness at which a definite diagnosis could be made from the blood of a patient. The evidence that this girl was the source of the epidemic was not absolutely conclusive, says Dr. Goldie, but it was very strongly suggestive. During the year no further houses were built by the council and only 14 by private enterprise. A certain number of houses were converted into flats, some of which are suitable for workmen's dwellings. The Housing Commissioner's estimate of the shortage of dwellings was considerably less than that of the local authority, but Dr. Goldie thinks that the census returns confirm the estimate of the local authority. The hours of bright sunshine during 1923 were 1268·2.

Lytham St. Annes.

Dr. John P. Litt, acting medical officer, submits the report owing to the resignation of Dr. G. C. Walker in March, 1924. During the year the Ministry of Health conducted an inquiry into the state of the mussel beds in the Ribble estuary. As these beds are all liable to sewage pollution, the Minister decided to make regulations prohibiting the sale of mussels from the estuary unless they could be effectively cleansed. As no place could be found in the estuary where the water was sufficiently clean to admit of cleansing the shell-fish by means of the ordinary methods of re-laying, the beds were closed in October, 1923. The veterinary inspector, Mr. J. R. Rigby, reports that the cattle in the borough dairy farms, numbering about 600, were examined quarterly. Mr. Rigby found among them three cases of tuberculosis of the udder and eight cases of tuberculosis of the lungs. All the affected animals were removed from the dairy herds. Six of the milk samples taken were seriously deficient in fat

Investigation of the matter disclosed very unequal inter-milking intervals—namely, eight hours between the morning and afternoon milkings and 16 hours between afternoon and morning. The vendors in every case were cautioned, but we are not told that they undertook to change their milking times. The sanitary inspector, Mr. H. Yates, hopes that the council will reconsider the limit of permissible black smoke adopted by them. Each chimney in the borough may now emit black smoke for two and a half consecutive minutes so long as there is an interval of 15 minutes between each emission.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 27TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 44; scarlet fever, 1805; diphtheria, 865; enteric fever, 91; pneumonia, 495; puerperal fever, 32; cerebro-spinal fever, 6; acute poliomyelitis, 31; acute polio-encephalitis, 3; encephalitis lethargica, 53; continued fever, 1; dysentery, 2; ophthalmia neonatorum, 124. There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 4 deaths from enteric fever, none from small-pox, 8 from scarlet fever, 28 from diphtheria, 6 from measles, 21 from influenza. In London itself the diphtheria deaths numbered 11, and the deaths from infantile diarrhœa 22.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

XX.—INCOME-TAX ASSESSMENTS:

HOW TO VERIFY THEIR CORRECTNESS.

By W. R. Fairbrother, F.S.S.,

ACCOUNTANT AND INCOME-TAX SPECIALIST.

Notices of assessment for income-tax in regard to the year ending April 5th, 1925, are being daily issued by the Revenue authorities. As any appeal against the amount of the assessment must be given in writing within 21 days of the receipt of the notice, it is obviously essential for the contents to be carefully checked at once. Attention should be directed not only to the amount of the assessment but also to the deductions, allowances, and reliefs claimable by the taxpayer. These were set out categorically in a previous article.[1] As the average medical man is subject to an assessment the nature of which is somewhat complex, it is very necessary that vigilance should be exercised.

Verification of Items.

This will best be achieved by following the order in which they are stated in the notice of assessment.

1. The amount of assessment as shown should accord with the return of profits previously made. If there is an increase in the notice an explanation should be asked for so that the discrepancy may be reconciled. It would be well to remember that even if the amount agrees with the return there are a number of somewhat unusual expenses which should have been allowed. These expenses should have included such well-known items as rent, rates, and water, repairs, assurance, drugs, instruments, bottles, lighting, heating, postages, stationery, telephone, periodicals, text-books, wages, and National Health Insurance. Included also in the expenses should have been the cost of car-running (or hire) expenses, whilst the amount allowable in respect of the cost of renewal of any car should have been deducted. Another item which is liable to be overlooked is the cost of board of locum tenens, whose salary is not so liable to be missed as an expense. The cost (or partial cost) of boarding servants, occasional servants, odd man or boy is also presumed to have been allowed. Still another point worth watching is that any income from public appointments is included in the general assessment as it is permissible to do so, and the resulting advantage is the receipt of one notice instead of a number varying with the sources of professional income.

2. The earned income allowance of one-tenth of the amount of the assessment should be shown. The limit to the amount of this allowance is £200.

3. The personal allowance of £135 is given in the case of a single person, whilst £225 is allowed to a married man. An interesting point to watch in this connexion is the allowance of the additional £90 even if married on the last day of the income-tax year. A still more interesting point, however, is to remember that a claim for refund of income-tax on £90 may be made if married before April 5th, 1924, and tax has already been paid for that year when single allowance only had been given.

4. The housekeeper allowance of £45 has been increased to £60 as from April 6th, 1924. This allowance is given in respect of persons taking charge of a widower's child, or acting as housekeeper merely, or in respect of a widowed mother having charge of a brother or sister in respect of whom the child allowance is given. Formerly a widower could not claim in respect of a housekeeper unless he had a child being looked after by such housekeeper, but this condition has been repealed.

5. The allowance in respect of children amounts to £36 for the first child and £27 for each other. The child must have been living on April 6th, 1924, to enable the allowance to be given in the current year, but it must not be assumed that if the child is born later the allowance is lost, for what is foregone in the first year is gained in the last year of claim—i.e., there are 16 annual allowances, and no more, given in respect of each child unless, of course, the proviso as to attending school beyond the age of 16 comes into play.

6. A deduction of £25 is claimable in respect of a dependent relative maintained by a taxpayer and who is incapacitated by old age or infirmity from maintaining himself or herself or is his or his wife's mother, whether incapacitated or not. A similar amount is deductable in respect of a daughter resident with the taxpayer and upon whose services he is compelled to depend by reason of old age or infirmity. No allowance is given where the dependent relative's total income is over £50 per annum.

7. After the deductions and allowances have been set against the assessment the net amount becomes taxable, and the first £225 of such taxable income is assessed at 2*s.* 3*d.* in the £, the remainder being at 4*s.* 6*d.*

8. When the total tax has been calculated ther should be deducted the allowance in respect of lif assurance, which varies from 2*s.* 3*d.* to 4*s.* 6*d.* in the £

9. If the first £225 of taxable income include items already taxed at the full rate at the source an allowance is made to bring the total deduction t the equivalent of £225 at 2*s.* 3*d.*

Professional Adjustments.

When all the foregoing checks have been institute it still remains necessary to watch the possibility of a adjustment in the assessment which is provided fo under various provisions in the case of profession Consideration may be claimed in such circumstance as the following:—

1. If a change in ownership takes place befor April 5th, 1925, the current year's assessment apportionable between the two practitioners on time basis.

2. Where practice is discontinued a claim shoul be made to have the assessment reduced to the actu profit of the income-tax year.

3. If practice was commenced within the last fou years, a claim may be made later for reduction the assessment to the actual profit of the year.

4. If the practice was taken over a claim may made for adjustment to the actual profit (instead the usual average) if such profit is less through som specific cause arising since or by reason of the takin over.

THE LANCET.

LONDON: SATURDAY, OCTOBER 11, 1924.

THE FUTURE OF HEALTH INSURANCE.

At a time when the Royal Commission is about to resume its labours it seems appropriate to review the present position of national health insurance, to see in what directions new ideas are pointing the way for future developments, and to discover the principles which should underlie a truly national scheme of health insurance. Sir George Newman's running commentary on the working of the Act, which we reprint in large part on p. 768, affords an admirable basis for discussion. That the present scheme has justified its existence was made evident in the whole-day conference[1] at the Bradford meeting of the British Medical Association, when representatives of every section of the community affected by the Insurance Acts expressed concurrence with its general principles. Among the advantages of the present scheme may be enumerated the following :—

1. It has helped to establish a health consciousness in the State.
2. It has revealed a volume of sickness among the workers not hitherto realised.
3. It has shown the effect of sickness on industry and the bearing of environment and conditions of industry on sickness incidence.
4. It has demonstrated the scope for coöperation between insurance practitioners and the medical officer of health.
5. It has pointed to the need for adequate hospital accommodation and for specialist and consultant services.
6. It has proved the possibilities of a thoroughly efficient medical service in providing an opportunity for the insured person to consult a general practitioner at the earliest stages of illness and for the practitioner to study disease in its beginnings.
7. It has brought the practitioner face to face with the problem of industrial efficiency.

Nevertheless, with all the progress recorded there is still no doubt that, as Sir William Glyn-Jones remarked at Bradford, the scheme has not redeemed the many promises made for it by its political parents at its conception. How the defects can be remedied and what immediate developments can be undertaken will doubtless be the chief concern of the Royal Commission. Many suggestions are being made, some of which affect the medical service, others the approved societies, the insurance committees, and the administrative machinery in general. The medical service could be strengthened by improving the conditions of work and the remuneration of the practitioners. This would increase the number of the doctors undertaking service, and, to quote Sir William Glyn-Jones again, make those practitioners as anxious to secure and retain insurance patients as they now are to secure and retain private patients. If the insured person could be trained to discriminate and to recognise efficient treatment, then the free choice of doctor would have its proper effect in the law of supply and demand. A natural corollary would be still further reduction of the "overcrowded" lists and a solution of the difficulties of the newly-qualified in getting an introduction to practice while they are young, vigorous, and efficient. The need for organisation in the medical profession is still insistent and there is scope for real scientific team work. Institutions in the nature of clinics and laboratories attached to special health centres should be established without delay. In his address last week to the students of Westminster Hospital, Mr. H. J. Waring, Dean of the Faculty of Medicine of London University, reminded us that modern medicine demands coöperative and institutional investigation and treatment, from which, he said, a pretty radical alteration in the National Insurance Acts must follow. Perhaps some one will introduce the four-year old report of Lord Dawson's Committee to the notice of the Royal Commission. The Consultative Council over which Lord Dawson presided was so impressed with the urgency which attaches to the orderly building of a constructive health policy, and with the close relationship which exists between medical services and the problems connected with Poor-law and local government, that they set forth in an interim report a model scheme of health centres. The general availability of medical services could, in their opinion, only be effected by new and extended organisation. This report is every whit as topical now as when it was issued.

The development of medical benefit will become more pressing than ever if and when the dependents of insured persons are included in the scheme. The conditions of service must be materially altered if the insurance practitioner is to perform the functions set out by Sir George Newman. How is the practitioner to deal with the "beginnings of disease" unless he has time to examine all his patients thoroughly? He would welcome any scheme of coöperation which rendered specialist and consultative assistance possible to his poorest patients. At present he is too much an isolated unit, and as such his usefulness and service are much curtailed. In the admitted difficulties of "certification," that nightmare of panel practice, a great deal more help might be given. The practitioner needs to learn the criteria on which the question of incapacity is decided; though memoranda are issued from time to time by the Ministry of Health, it is really in concrete cases that the principles need to be demonstrated. The position is complicated by the fact that at present different standards are employed by practitioners, referees, and approved societies. The nature of his relationship to the approved societies needs to be brought more clearly to the knowledge of practitioners. There is, in fact, room for much greater coöperation, which can hardly come to pass until more sympathetic relations are set up between them. The machinery of approved society administration needs overhauling. It is doubtful whether these societies do now serve the highest interests of the State; their aims are too narrow and their views too cramped for the purposes of a great health insurance scheme. But there is welcome evidence in some quarters that a wider view is being taken, and it may still be possible to enlist the services and coöperation of the societies in the great task of preventive medicine. Mr. Alban Gordon, whose book entitled "Social Insurance" is reviewed on p. 753, himself the secretary of an insurance society, criticises severely the administration by approved societies and such anomalies as the inadequacy of the benefits, the overlapping of the thousands of separate societies, the neglect of preventive measures in disease, and the lack of personal touch in administration. He suggests that medical benefit should be taken out of the Act altogether, inasmuch as the prevention of illness and its prompt treatment when recognised do not form a logical section of any organisation taking charge of sickness and disablement benefits; these are self-contained affairs, which rest on an actuarial basis and can be restricted to persons paying contributions. None of this holds good for what is implied by medical benefit. To take medical benefit out of the Act, a suggestion brought forward and endorsed at Bradford, would involve the abolition of insurance committees. Many people, on the other hand, are satisfied that in the larger towns and counties these committees have proved their efficiency in administering army and navy insurance funds, and the affairs of deposit contributors. This is another problem for exploration by the Royal Commission. Lastly, there is the insured person who must be educated to play his part in the scheme. The doctor is still his best friend, but some steps appear to be necessary to secure a useful discipline to enable the doctor to render his full service, both to the individual and to the State. At present the free choice of doctor and the unlimited right to transfer enjoyed by the insured person are working to the vicious end of making the doctor his slave instead of his adviser and guide. The responsibility of the practitioner to his patient is great, but his duty to the State is still greater.

◆

THE GROWTH OF THE JAWS.

Sir Arthur Keith told the students of the Royal Dental Hospital last week that Nature can be trusted to give mankind the dentition it deserves. Our knowledge of the development and growth of the jaws is not very complete, and what is known is not applied. In the earlier part of the year the Dental Board arranged for a course of lectures on this subject to be delivered in various centres. These have now been published in book form, and comprise contributions from Profs. E. Fawcett and J. C. Brash, Mr. G. Northcroft, and Sir Arthur Keith. The volume forms a monograph on the growth of the jaws, both normal and abnormal, of value and interest not only to the dentist, but to the anatomist and anthropologist. It is no disparagement to the masterly review of the development of the jaws by Prof. Fawcett, or to the suggestive chapter by Mr. Northcroft, to say that the chief interest of the reader will centre on the two lectures by Prof. Brash and the fascinating speculations of Sir Arthur Keith. The chapters on the growth of the jaws and the genesis of deformities of the jaws, by Prof. Brash, embody a large amount of original work which will make it necessary to revise some of our previous conceptions of the mechanism of deformities of the jaws. Modern knowledge of the principles underlying mandibular growth commenced with the classical work of John Hunter, who demonstrated very clearly the chief sites of growth and was one of the first to employ the method of superimposition of jaws at different ages. At a much later date Sir John Tomes and G. M. Humphry, working independently, showed for all time the way in which the mandible increases in size from infancy to adult life. It is a striking tribute to their accurate observations that the general principles enunciated by them still hold good, even although some of their conclusions need to be modified. Brash has used on pigs the "madder" method, in which the bones are stained red. His work confirms the views of Hunter and Tomes that growth of the mandible is a combination of surface addition of bone with surface absorption. His specimens show to an extent not always realised how great is the amount of absorption of bone which goes on concurrently with the addition of bone. Prof. Brash challenges the long-accepted view that the alveolar arch of the deciduous teeth is the same as that of the successional permanent teeth. By means of measurements J. Tomes sought to show that the arch of the ten front teeth did not alter and that the greater width of the adult jaw as compared with that of a child was accounted for by additions to the outer surface of the bone. There can be little doubt that in this respect Tomes was wrong and that the alveolar arch of the permanent teeth is definitely larger than the deciduous arch. Both J. F. Colyer and G. Franke, by means of measurements of models of the jaws of the same individual at different ages, had come to this conclusion, which is now confirmed by Brash.

The problem of the growth of the maxilla is complicated both by its connexions with other bones and by the part it plays in the growth of the nasal cavities. Up to quite recently our knowledge of the way in which the maxilla grows was very slight, and it was not until Sir Arthur Keith and G. Campion published their remarkable paper on the Mechanism of Growth of the Face,[1] in 1921, that the gaps in our knowledge began to be filled. This paper gave a new orientation to our ideas on the growth of the face, and has already become classic, even although its full significance has not yet been realised. Prof. Brash acknowledges in handsome terms his indebtedness to their work, which is, to quote his words, "a first essay in a difficult and practically uninvestigated field of knowledge." Keith and Campion chiefly studied the factors involved in the normal growth of the face; Brash attempts to carry the work a stage further by applying the principles of normal growth to account for the genesis of deformities of the jaws. Keith and Campion used extensively the method of superimposition of drawings to determine sites of growth increment. Brash, while admitting the general value of this method, points out that it has its fallacies. His own conclusions, drawn both from madder specimens and from measurements of human jaws at different ages, do not agree in all respects with those of Keith and Campion, yet the general agreement is striking and affords valuable confirmation of their work. In general, it may be said that the growth of the maxilla is a complicated combination of surface addition with sutural growth. The relative importance of these two factors has not been fully worked out, but it is possible to estimate with some degree of accuracy the amount of growth which occurs at the different sites of growth activity. An interesting section of Brash's work is that which deals with growth of the palate. The term "growth in height of the palate" is a misleading one, for actually the level of the palate descends. This is brought about by addition of bone to the under surface of the palate, accompanied by absorption of bone on the upper or nasal surface. The greater depth of the palate of the adult, as compared to the shallow palate of the infant, according to Brash, is due to downward growth of the alveolar process. Both palate and alveolar bone are themselves growing downwards, but the alveolar growth outstrips that of the palate and it is this factor which determines the height of the palate. This conception has an important bearing on the way in which the high palate, which so often accompanies the adenoid facies, is produced. It has often been maintained that in this type of deformity the palate is forced upwards by external pressure due to mouth-breathing which is the more readily facilitated by the lack of growth of the nose owing to nasal obstruction. BRASH vigorously combats this view by a wealth of convincing argument. The high palate, which is the commonest of dental deformities, is due either to an excessive downgrowth of the alveolar process or to decreased growth of the vault of the palate, or to a combination of both. The important point which BRASH brings out is that the increased height is present at an early age, certainly before the age of 8 years. The narrow dental arch which is always present in the high palate is to be accounted for by the fact that in normal jaws the alveolar bone grows both downwards and outwards, whereas in the abnormal jaw the growth is chiefly vertical or may even be inwards. Comparative figures show that the actual amount of growth change in both normal and abnormal jaws after the age of 8 is about equal. BRASH considers that the early age at which deformities of the jaws become established puts out of court any explanation of their ætiology based on mechanical grounds. He suggests that their causation must be due either to hereditary factors or to nutritional factors. These latter may act directly or by influencing the glands concerned with the regulation of growth.

---

[1] Dental Record, 1922.

To the orthodontist concerned with the prevention and treatment of irregularities of the teeth and jaws this book, together with the earlier paper of KEITH and CAMPION, should prove indispensable. The volume is a notable addition to our knowledge of a particularly difficult subject, and should do much to place that important branch of dentistry which deals with the treatment of dental deformities on a more rational basis.

◆

THE MAUDSLEY HOSPITAL.

THE progress of the energetic early treatment of insanity, which is now being carried on at the Maudsley Hospital, is being watched with interest, and the first annual report is therefore of great importance. It is, perhaps, hardly necessary to explain that the hospital was built by the London County Council out of funds left by the late Dr. HENRY MAUDSLEY, the first among psychologists to lay stress on the fact that mental disorder may often be an expression of physical illness, and therefore amenable to appropriate treatment. A provision in the London County Council Act, 1915, enables the patients to be admitted on a voluntary basis; no person under certificates is received, and no patient is certified within the walls of the institution should removal to another mental hospital eventually prove advisable. Persons "having a legal settlement in the County of London" are admitted for a payment in proportion to their means; the full maintenance-rate (£5 per week) is charged to those coming from elsewhere. Further requirements are an undertaking by some responsible person as to the provision of other arrangements for care—if necessary in less than 24 hours from receipt of notice, and the approval of the medical superintendent, or his deputy, as to the medical suitability of the proposed patient, this generally involving a personal interview. The former condition has been waived in a few cases, and indeed it is evident that in every way the staff at the hospital and the corresponding department in the County Hall have made every effort to avoid unnecessary formalities and delays. In regard to "medical suitability," it is hardly surprising that difficulties should have arisen: relatives, and practitioners acting under pressure from them, naturally minimise such features of a case as are likely to render it an unsuitable one for admission, and the condition of a personal interview with the patient is regarded as necessary unless the hospital is to become a "clearing-house to the mental hospitals of the county."

The first essential for comprehending the work which is being done is to note the composition and numbers of the staff. In a hospital of about 150 beds, with private rooms for female patients and with an out-patient clinic, there have been no less than 18 medical officers working during the year. There are five permanent resident officers; four medical officers at a time from other mental hospitals under the Council are being seconded, with the pay of their rank, for periods of three months to the Maudsley for either clinical or pathological work; and in addition "an indefinite number of medical men or women (preferably those with previous experience of nervous and mental disorders) may be appointed as voluntary clinical assistants on either part-time or whole-time basis." Eleven such appointments have been made, there being an average of six assistants working at any given time, and even with this assistance we learn that the work of the regular medical officers remains extremely heavy. This indicates what is involved when psychotherapy is undertaken on a large scale, and when neuroses are dealt with seriously. The total number of cases treated during the year was 1012, of whom 894 attended the out-patient department. The number of admissions was 452, and of those discharged after a full course of treatment (i.e., not prematurely for financial or other reasons) 35 per cent. were recovered, 35 per cent. were improved, and 30 per cent. were not improved. Those interested in such projects as are typified in the Maudsley Hospital will look with keen attention to the types of case admitted, for herein lie at once the greatest difficulty of such work, and the clue to any success it may achieve. No very definite indications are given by Dr. EDWARD MAPOTHER, the medical superintendent, as to the criteria of suitability which have been adopted; the question is obviously not a simple one, and every rule must have its exceptions. We understand, however, that the omission was due to the exigencies of space in the report, and that Dr. MAPOTHER proposes to discuss in a supplementary article the advantages and limitations of treatment on a voluntary basis and the types of suitable cases which actually present themselves. General paralytics, it may be gathered from the report, are admitted for the purpose of applying recently suggested methods of treatment; the appearance of dementia præcox in the statistical tables indicates, we are told, the difficulty of prognosis in the initial stages, the diagnosis having been reluctantly reached after observation in cases which at first seemed of another and more hopeful type. The nature of the year's admissions is broadly as follows: alcoholism, 12 cases; dementia præcox, 34; paranoid types, 32; manic-depressive types, 13; depression, 92; neurasthenia, 23; hysteria, 21; anxiety states, 57; and obsessional states, 21 cases. Various tables afford exact information as to the duration of the attack, accompanying physical conditions, and the duration and result of treatment; another table correlates diagnosis and method of disposal.

Of the therapeutic resources of the hospital it is enough to say that physical treatment, as exemplified by baths and massage, is employed to a great extent, while the close connexion between the Maudsley and King's College Hospital provides for much special work; the dietary is particularly studied from the points of view of individual requirements and attractiveness; great stress is laid on open-air treatment, by night as well as by day, and the minimum possible restrictions on liberty are imposed. A variety of research has been undertaken. The subjects studied include basal metabolism, blood-sugar variations, including those induced in response to drugs, liver function, the oculo-cardiac reflex, the effect of drugs on the cytology of the blood, the reaction of the vascular system to the ingestion of food, and to postural and temperature changes, variations in the power of oxidising phenols, and the psycho-galvanic reflex. The special treatments employed have included gland therapy (seven single and two compound gland preparations being used, with no very convincing results), injections of insulin in cases where pancreatic function had been disturbed, the employment of arsenical and bismuth compounds, and inoculation with malaria in the treatment of general paralysis, and last, but not least, psychotherapy, including full courses of psychoanalysis. These observations are intended only to indicate the type and method of the work which has begun at the Maudsley Hospital. It is in a unique position, at least as regards England. Its possibilities are still untried, and it is important that every practitioner, particularly in London, should be and remain aware of its existence and purpose.

Annotations.

"Ne quid nimis."

THE SUPPLY OF DRUGS TO ADDICTS.

NEXT month, as we noted last week, an international conference is meeting in Geneva with a view to limiting the production of harmful drugs to the actual medical and scientific needs of the world. Information as to the amount required for legitimate needs is accumulating. The results of an American narcotic survey have just been published; a county in Maryland was chosen for the purpose owing to its remoteness from the sea-coast, its largely rural character, its diversified population, and its easy access from Washington. The records were studied of all the narcotic registrants in the county of Allegany during the period July 1st, 1922, to June 30th, 1923, which involved visits to 69 physicians, 12 dentists, 20 retail and 3 wholesale pharmacists, 1 veterinarian, and 5 hospitals and sanatoriums. The total opium equivalent of opiates used was 69·81 pounds of opium and the total cocaine equivalent was 293·03 pounds of coca leaves. Taking the population of the county as 69,938 from the 1920 census, the per capita consumption works out at 6·98 gr. of opium and 29·32 gr. of coca leaves. On the same basis, to supply the entire United States with its population of 106 millions would require annually 105,697 pounds of opium and 443,988 pounds of coca leaves. The Washington Public Health Department regards these data as representing fairly accurately the medical requirements in opiates at the present time, but not in the case of cocaine, since most of the dentists who then used cocaine have since discontinued its use in favour of the synthetic local anæsthetics.

In this country the difficulty of withholding morphine and heroin from those addicted to their use is pressing very hardly on the medical man. The Minister of Health has now appointed a Committee with the following terms of reference:—

> To consider and advise as to the circumstances, if any, in which the supply of morphine and heroin (including preparations containing morphine and heroin) to persons suffering from addiction to those drugs may be regarded as medically advisable, and as to the precautions which it is desirable that medical practitioners administering or prescribing morphine or heroin should adopt for the avoidance of abuse, and to suggest any administrative measures that seem expedient for securing observance of such precautions.

The members of this Committee are: Sir Humphry Rolleston, President of the Royal College of Physicians; Sir William Willcox, Honorary Medical Adviser to the Home Office; Dr. J. W. Bone, representing the British Medical Association; Dr. R. W. Branthwaite, Board of Control; Dr. G. M. Cullen, Scottish Board of Health; Prof. W. E. Dixon, Reader in Pharmacology, Cambridge University; Dr. John Fawcett, Physician, Guy's Hospital; Dr. A. Fulton, Divisional Medical Officer, Ministry of Health; and Dr. J. Smith Whitaker, Senior Medical Officer, Ministry of Health. The chairman of the Committee is Sir Humphry Rolleston, and the joint secretaries are Dr. E. W. Adams and Mr. R. H. Crooke, to whom all communications should be addressed at the Ministry of Health, Whitehall, London, S.W. 1.

DANGEROUS DRUGS IN GENERAL PRACTICE.

THE current issue of the London Panel Committee's *Gazette*, which circulates among practitioners on the panel in the County of London, contains a very clear statement of the obligations of the practitioner arising from the Dangerous Drugs Act, 1920, and the regulations made under it. The drugs affected are morphine, cocaine, ecgonine, and diamorphine with their respective salts, also medicinal opium with its preparations, and are included under the Act when the finished preparation contains more than one-fifth per cent. of morphine and more than one-tenth per cent. of cocaine, ecgonine, or diamorphine (heroin). Prescriptions containing these drugs must be written, dated, and signed by the practitioner; in the case of private prescriptions his address must be given, but this is not obligatory on insurance prescriptions. Prescriptions in all cases should give the name and address of patients. Practitioners may obtain from chemists drugs for personal administration, and orders for these should give the practitioner's name and address in writing. Messengers should be provided with documentary evidence that they are entitled to receive such drugs. Practitioners have to keep records of the purchase and sale of dangerous drugs other than for personal administration or given under direct supervision. Any prescription containing when finished less than a certain percentage of the drug may be dispensed as before the Act. The upper limit in the case of some of the more usual preparations is as follows:—

	Per ounce.	Per drachm.
Chlorodyne, B.P.C.	190 ♏	22 ♏
Cocain. hydrochlor.	0·4 gr.	0·05 gr.
Diamorphin. hydrochlor.	0·4 gr.	0·05 gr.
Liq. morph. acet.	120 ♏	15 ♏
,, ,, hydrochlor.	106 ♏	13 ♏
Morphin. alkaloid (cryst.)	1·0 gr.	0·12 gr.
,, acet.	1·2 gr.	0·15 gr.
,, hydrochlor.	1·15 gr.	0·14 gr.
,, sulph.	1·12 gr.	0·14 gr.
,, tartr.	1·12 gr.	0·14 gr.
Tr. opii	95 ♏	11 ♏
Tr. chlorof. et morph. co.	95 ♏	11 ♏

Certain preparations containing opium or its derivatives are outside the regulations altogether—viz.: Tr. camph. co.; tr. chlorof. et morph. (chlorodyne B.P. '85); tr. opii ammon.; troch. morph.; troch. morph. et ipecac. Other preparations are exempted on the understanding that if any other medicament is mixed with them, and the percentage of dangerous drug exceeds the limit, the product then comes within the regulations. These are: Cereoli iodof. et morph., B.P.C.; empl. opii, B.P., 1898; lin. opii, B.P.; lin. opii ammon., B.P.C.; pasta arsenical., B.P.C.; pil. hydrarg. c. opio, B.P.C.; pil. ipecac. c. scill., B.P.; pil. plumbi c. opio, B.P.; pil. digitalis et opii co., B.P.C. (Heim); pil. hydrarg. c. cret. et opii, B.P.C. (Hutchinson); pulv. cret. aromat. c. opio, B.P.; pulv. ipecac. co., B.P. (Dover's powder); pulv. kino co., B.P.; suppos. plumb. co., B.P.; tab. plumb. c. opio, B.P.C.; ung. gall. c. opio, B.P. (gall and opium ointment); ung. gall. co., B.P.C.

All these points can be found in official circulars, but it is a boon to the practitioner to have them set out thus.

EUGENICS BY LEGISLATION.

THE Ministry of Health has returned a cautious negative to a Parliamentary question concerning possible legislation on eugenic lines. As our Parliamentary correspondent notes, Mr. Black had asked whether, in view of the financial commitments of the nation in respect of persons who through physical or mental deficiency become a charge upon public funds, a Royal Commission would be appointed to advise upon the restriction of procreation of children by unfit parents. While this country is not yet prepared for advanced eugenic legislation, it is interesting to note what legislatures are doing elsewhere. A recent volume of the Society of Comparative Legislation, containing summaries of the laws passed in different parts of the world during 1922, shows several examples of American enactments on this topic. The State of Nebraska, for instance, forbids the marriages of persons afflicted with venereal disease, and insists that no one adjudged afflicted with hereditary epilepsy or insanity shall marry unless first submitting to a sterilising operation ; applications for licences to marry must be accompanied by affidavits of freedom from venereal disease. Montana provides for the sterilising of inmates of what are euphemistically called "custodial institutions," who are insane or feeble-minded or idiots or epileptics. An essential and certainly desirable feature of the Act is the insistence on adequate medical advice ; there is a hearing before a board with a right of appeal therefrom to a court of law. These American provisions are, of course, by no means the first of their kind. As long ago as 1895 Connecticut forbade the marriage of epileptic or feeble-minded persons under penalty of a minimum term of three years' imprisonment. Ten years later the Act was attacked in the Supreme Court as being unconstitutional but was upheld, though it was subsequently modified. Wisconsin, Maine, and Delaware are other States which have passed similar legislation. The underlying principle is the same, but the measures differ in that sometimes they actually make marriages void, sometimes they merely punish those who marry. Another American type of eugenic enactment is aimed not so much at preventing the birth of unfit children as at putting an end to sexual assaults by degenerates. Thus California in 1922 empowered the criminal courts to direct an "operation to prevent procreation" to be performed on persons convicted of carnal abuse of girls under ten years of age. Indiana, Iowa, and other States have passed similar Acts in the past, but the courts have sometimes held the laws to be contrary to the constitution ; in one case the operation was held not to be a "cruel" punishment, in another it was held "cruel and unusual," and therefore unconstitutional. This supervision of legislation by judges is always a little puzzling to us in this country where legislators are unhampered by a rigid written constitution. We have not, however, hitherto heard much of eugenics at Westminster, unless we are to ascribe to a vague eugenic instinct the reluctance of certain legislators to pass such measures as the Deceased Wife's Sister's Bill.

THE RESULTS OF CONSERVATIVE TREATMENT OF POTT'S DISEASE.

NOW that the treatment of Pott's disease is becoming operative, and Albee's operation is extensively employed, it is most desirable that, for the purpose of comparison, information should be available as to the results obtained by more conservative measures. For it is obvious that there is no indication for operative treatment, however good its results, if patients recover as often, as soon, and as permanently under less heroic measures. To provide such material for comparison, Dr. Santeri Leskinen,[1] of Helingsfors, has collected the evidence obtainable in connexion with 241 cases of Pott's disease treated at his hospital on conservative lines in the period 1895–1920. As many as 21 of these patients died in hospital, and of the remaining 220, only 137 could be traced. There were 126 males to 115 females, and 68 per cent. were between the ages 1 and 10. The cervical vertebræ were involved in 16·2 per cent., the thoracic vertebræ in 56·4 per cent., and the lumbar vertebræ in 27·4 per cent. Thus, the thoracic vertebræ were involved in more than half the total number of cases. But when the incidence of the disease in each vertebra was calculated, it was found that it was highest for the lumbar vertebræ, each of which accounted for 13·2 per cent. of all the cases, whereas the corresponding figures for each thoracic and cervical vertebra were 11·3 per cent. and 5·5 per cent. respectively. In addition to the 21 patients dying in hospital, there were 43 who died after discharge. Thus, the mortality among the patients who could be traced was as high as 40·5 per cent. It was much higher for males than for females, the respective figures being 50 per cent. and 32 per cent. Tuberculosis or its sequels was the cause of 57 of the 64 deaths. The survivors who were traced were classified according as they were still ill, fairly well, or cured. The figures for these three classes were, in the order named, 12, 17·1, and 30·4 per cent. respectively. It will thus be seen that with a mortality of 40·5 per cent., and a complete recovery-rate of only 30·4 per cent., there was much room for improvement on the results of conservative treatment. The best results were obtained in disease of the cervical vertebræ, only 26·3 per cent. of the patients having died, whereas 68·5 per cent. had completely recovered. Disease of the thoracic vertebræ responded least satisfactorily, the mortality being 46·3 per cent. and the recovery-rate 21·1 per cent. in this class. When the patients were classified according to their ages, it was found that the mortality was highest in the first two decades, in which it was 41 and 44·8 per cent. respectively. It was lowest in the third decade, in which it was 30·8 per cent. After the age of 40 the mortality became higher again. The average duration of treatment in hospital was eight months for the patients who were cured, six and a half months for the patients who remained fairly well, and seven and a half months for those who remained ill. It is sincerely to be hoped that operative treatment may give better results.

A CARDIOVASCULAR SYMPOSIUM.

ATTEMPTS to reconcile the rapid advance of knowledge with the endeavour of the busy medical practitioner to make the best use of the scanty hours he can devote to study are always interesting. Such we believe is the objective of the editors of the symposium now being issued by the *Medical Journal and Record* of New York. The example we have recently received[1] deals with cardiovascular diseases, and we can readily believe that it will be welcome. It contains four articles which, without in any way attempting to provide a complete survey of the modern views on diseases of the heart and blood-vessels, give useful information on four big subjects which should be valuable to every practising physician who reads them. The opening article by Dr. T. Parsons-Smith perhaps errs on the side of complexity ; his subject is bradycardia, and whilst recognising the necessity for electro-cardiography in the differential diagnosis of many of the underlying causes of this condition, we feel that he may have laid undue emphasis on the interpretation of electro-cardiograms. The omission of references from his original article diminishes its value to the specialist. The other articles include a valuable dissertation on hypertension by Dr. Ernst P. Boas, and an excellent essay by Dr. S. Neuhof on the use of quinidine in private practice. This author finds that by giving 5 grains on the first day and three 5-grain doses on the second and third days, with careful examination by the family physician, the drug can be safely used in the patient's own home. In all cases with tachycardia, a preliminary course of digitalis was given, and, in all cases, symptoms of idiosyncrasy, such as vomiting, diarrhœa, tachycardia, were carefully watched for. After the third day of quinidine, the consultant again saw the patient and the nature of further treatment was decided. Dr. Neuhof has experienced the same uncertainty of effect that has been generally recognised; but he reports no untoward results from the treatment of private patients on the lines indicated, and his article is an effective illustration of how the use of a valuable drug may be extended without danger.

RETINITIS PIGMENTOSA.

RETINITIS pigmentosa is one of those diseases the pathology of which is still a subject of keen debate. To recapitulate the main facts which any theory, to be tenable, has to explain: The disease is slowly progressive, intractable to treatment, and is liable to occur in several members of a family. Its most typical ophthalmoscopic appearance is a passage forwards into the anterior layers of the retina of cells belonging to the hexagonal pigment layer which are normally situated at the back of the retina immediately in front of the choroid—this phenomenon first becoming evident in the mid-peripheral region. A constant symptom, even in early cases, is night-blindness; and the visual field nearly always shows a ring scotoma corresponding to the ring of abnormal pigment in the mid-peripheral zone. Two antagonistic theories have been and are still held to account for these phenomena. On the one hand, the atrophy of the outer layers of the retina is supposed to be secondary to changes of a sclerosing character in the choroidal blood-vessels on which their nutrition depends. On the other hand, it is suggested that the degeneration of the retinal elements is primary and the sclerosis of the vessels of the choroid a secondary phenomenon. Treacher Collins put the case for this view five years ago in an important paper which was much criticised at the time, but which has never been satisfactorily answered.[1] In his view these cases are analogous to those degenerations of tissue due to defective vitality to which the late Sir William Gowers gave the name "abiotrophy." These diseases present characteristic features, says Collins, wherever they occur, which differentiate them as a class from other affections. These features may be summarised as follows: 1. The tissue which is affected is one that has attained mature development and which then retrogresses. 2. The condition is one which commonly involves several individuals of the same family, either members of the same childship or members of different generations. 3. The parts affected are usually bilateral and the extent of disease is limited by definite anatomical landmarks (as, for instance, in the nervous system by a certain set of neurons). 4. The changes produced are progressive so far as the anatomical limits of the tissue permit, and recovery does not take place. 5. The tissues involved are those which have attained a high degree of specialisation. In all these respects a typical case of retinitis pigmentosa appears to conform. Physiologically the pigment in the hexagonal pigment cells is possessed of the power of amœboid movement which is exercised under the stimulus of light. In the normal retina, however, a barrier is formed by the external limiting membrane through which the pigment cannot pass. Atrophy of the rods and cones causes openings in this membrane through which the pigment is free to wander. According to this view, the sclerosis of the chorio-capillaries which is so often found is not the primary affection but is secondary to the retinal atrophy, and Collins supports his argument by citing the fact that the pathological examination of the eyes from four undoubted cases of retinitis pigmentosa in different stages of the disease by independent observers, has shown that it may occur without any discoverable sclerosis of the choroidal vessels.

With regard to the particular region of the retina first affected in typical cases, the advocates of the choroidal theory connect the ring scotoma and the distribution of the pigment in the periphery with the anatomy of the ciliary arteries, the disease commencing at a part where the supply of choroidal blood is least efficient.[2] Collins finds the evidence for this view insufficient and prefers to connect the distribution of abnormal pigment and scotomata with the fact that different regions of the retina are developed at different periods of fœtal life. "It appears that the neuro-epithelium of the ultimate central area of the human retina is of later formation than that of the parts around and that of the part immediately around the central area is the first to attain its full development." It is this paracentral area that is affected first in typical cases of retinitis pigmentosa, whereas the central area which is the last to be developed is usually the last to be involved. In the interval since this theory of "abiotrophy" applied to retinitis pigmentosa was first put forward, we have had but little fresh light on the problem. Mr. M. L. Hepburn, in an article in the September issue of the *British Journal of Ophthalmology*, supports the choroidal origin of the disease, and pertinently remarks in connexion with Collins's paper that he cannot quite follow the argument that perfectly healthy pigment and pigment epithelial cells should wander away from their normal position, merely because their anatomical boundaries in front are destroyed. The subject is complicated by the fact that there are certain cases of undoubted choroiditis in which the signs and symptoms are very similar to those of typical retinitis pigmentosa. Occasionally, it is very difficult to make the distinction between the two. If the supporters of the choroidal theory are right, there is no distinction in kind but only in degree. On the other hand, if the theory of "abiotrophy" is ultimately confirmed, the resemblance is accidental.

AN AD HOC RESEARCH.

Two members of the Harmsworth family have contributed a sum of £25,000 to endow a research fund in memory of Mr. R. L. StJ. Harmsworth, who died of infective endocarditis. The object of the fund is to investigate, and, if possible, to solve, the problem of this disease; to this end the trustees of the fund will be advised by a scientific committee consisting of Sir Thomas Lewis, Sir E. Cooper Perry, Sir Thomas Horder, and Dr. Mervyn H. Gordon. In the first instance the work to be undertaken by the fund will be (1) the collation of facts as yet known concerning the disease, (2) a close study of cases at present under observation and treatment, and (3) research along any hopeful lines suggested by members of the scientific committee. Grants may be made to individual workers in this country or abroad, subsidies paid to workers whose present efforts are directed in the right direction, to others who undertake special new lines of research, and to those who contribute statistics, data, or results of private experiments. It is proposed to spend in this way the whole net income of the fund each year and to close the fund at any time by the grant of the whole of the capital to a worker adjudged (to quote the terms of the award) to have finally disposed of the present obscurity overlying our knowledge of the disease, and thus to give the profession "control" over the disease. Sir Thomas Horder, in a report to the trustees, gives an account of a typical case of infective endocarditis which is sufficiently graphic to set out here in full.

> B. J., a young man of 28 years, comes under observation because of some general malaise following a short febrile illness which was thought to be "influenza." The temperature incident upon the latter disease does not subside, but persists without any obvious reason. Careful examination reveals no signs of any pulmonary disease, and the only structural change present is a valvular defect known to have existed since an attack of rheumatic fever at the age of 18 years. This defect had caused no handicap hitherto and even now there are no signs of any disability of the heart. Prior to the "influenza" the patient considered himself quite fit, although inquiry elicits the fact that this illness was not of sudden onset but preceded by some sweating at night,

[2] Nettleship: Royal London Ophthalmic Hospital Reports, vol. xv., part iii., January, 1903.

a few "rheumatic" pains in the limbs, and a sense of unfitness. On one occasion, six weeks before the "influenza," there had been a sudden sharp pain in the tip of one finger lasting for an hour or two, and leaving a small patch of dusky-red discoloration, which disappeared entirely after a couple of days.

Critical examination shows that the patient's complexion is sallow and slightly anæmic, and that there is a slight but definite enlargement of the finger ends—the so-called "clubbing" of the fingers. There has been a little loss of weight. The mental state is sanguine. Already, with this clinical picture, a suspicion of infective endocarditis is strongly aroused. The blood is cultivated, but no microbes are isolated from the specimen taken. A month later, however, two other negative cultures being made in the meantime, a streptococcus is isolated from the circulation, having characters that are recognised as being commonly met with in the disease. By this time the patient's condition has deteriorated a little; the temperature has persisted without a break, though there have been periods of a few days at a time when, perhaps as the result of some treatment, the height of the fever has been much less. There have been two or three recurrences of the sudden pains in the finger ends, and once a similar event occurred in one toe. On one occasion there was a little blood in the urine, clearing away in less than a week. A few minute hæmorrhages have been noted in the skin about the neck ("petechiæ"). The anæmia is rather more marked.

Despite all efforts at treatment—an open-air life, good food, tonic measures, two or three transfusions of blood from a suitable "donor," and a trial of several different types of sera and vaccines—there is a steady and progressive decline in the patient's condition. The disease, dating this from the time when the sweats and general malaise began—the "influenza" being now regarded as merely an exacerbation of the toxic state dependent upon the infection—has by this time lasted some six months. Although the patient is still optimistic, it is obvious, even to the uninitiated, that he is a stricken man. Examination of the heart shows no great change, but the signs of the old valvular mischief are more obvious and the heart muscle is now dilated.

Two months later the kidneys show signs of failure; albumin is present in the urine and there is slight dropsy present. The petechiæ have increased considerably in number. A good deal of flesh has been lost. Further blood cultures yield the same streptococcus on every occasion, and in increasing numbers. A state of drowsiness sets in, with other evidence of kidney insufficiency, and the patient sinks into a state of uræmic coma and dies. The disease has lasted for nine months, and its anticipated course and duration have been little, if at all, influenced by treatment.

Sir Thomas Horder concludes that the disease is in effect a form of chronic septicæmia associated with a septic focus in the wall of the heart, the brunt of the attack falling now on the kidneys, now on the brain, the lungs, or the heart itself. It attacks valves damaged by rheumatic fever, less frequently by other agents, and the influence of prolonged physical and nervous strain is an important factor in inducing the condition, hence the rise in incidence following the war. Dr. Gordon contributes a pathological note on the lesions and contrasts the uniform fatality of the disease once developed in the human subject with its comparatively feeble virulence in animals. From this it appears that infective endocarditis is not so much a primary disease as a sequel to previous disease, injury, or other depressing factor. One promising line of research should be an attempt to define the degree of the patient's specific resistance to the particular micro-organism, along which preliminary work has already been done on behalf of the Medical Research Council by Dr. P. O. Ellison, Dr. G. Bourne, and Dr. P. Hamill. Another is to inquire why the disease should select for attack the valves of the heart, and a third to determine the particular factor in the specific defence that breaks down. We have the opportunity of publishing this week a study of the incidence of infective endocarditis in congenital heart disease, made at the Middlesex Hospital by Dr. H. E. A. Boldero and Dr. D. E. Bedford, in which the interesting suggestion is made that the changed composition of the blood after passing through the lungs may explain the preponderance of left-sided lesions. It is, we understand, hoped that the research fund will be considered an appropriate medium for the collection of information. The secretary of the Scientific Committee is Dr. Seymour Price, at 41, Sloane-gardens, London, S.W.1.

THE ROYAL COMMISSION ON LUNACY.

THE Royal Commission on Lunacy Law and Administration and Mental Disorder held its first sittings at Westminster this week under the chairmanship of Mr. H. P. Macmillan, K.C. Under its terms of reference, which concern England and Wales only, the Commission is (1) to inquire into the existing law and administrative machinery in connexion with the certification, detention, and care of persons who are, or are alleged to be, of unsound mind; and (2) to consider the extent to which provision is, or should be, made for the treatment without certification of persons suffering from mental disorder, and to make recommendations. At the opening session the Board of Control, represented by Sir Frederick Willis, its Chairman, Mr. S. J. Fraser Macleod, K.C., and Dr. C. H. Bond, submitted evidence as to the existing working of the Lunacy Acts. The Board is itself the legal successor of the Lunacy Commission appointed in 1845 to inquire, as the Chairman of the Commission elicited, into the persons and not the property of persons of unsound mind. Detailed figures were given which may be thus summarised. The total number of insane patients on Jan. 1st, 1924, was 130,334, distributed as follows: in county and borough mental hospitals, 103,892; in registered hospitals, 2139; in licensed houses, 2797; in naval and military hospitals, 171; in the criminal lunatic asylum at Broadmoor, 785; in ordinary Poor-law institutions, 11,323; in metropolitan district mental hospitals, 5266; in private single care, 417; and in outdoor relief, 3544. The admissions to public mental hospitals during 1922 numbered 20,367, of whom 58·5 per cent. were admitted from Poor-law institutions, 37·2 per cent. direct from their own homes, and 4·3 per cent. from other sources. On Jan. 1st, 1924, the vacant bed space in mental hospitals was sufficient only for 4754 patients, while the average yearly net increase was 3565. Hence a considerable shortage of mental hospital accommodation existed. The Board felt that better use could be made of the existing accommodation if all the workhouse and mental hospital accommodation were under the control of the visiting committees, which in any case might through their expert medical staff supervise and direct the operation of the guardians. Mr. Macleod, at the Chairman's request, outlined to the Commission the course which would be adopted if a person in the room became of unsound mind. All lunacy orders were, he said, examined by the officials of the Board, and of the 30,000 certificates presented in the course of the year, few were found to be defective. Dr. Bond remarked that when an order was returned it was because it was so worded that the Board could not ascertain whether the symptoms mentioned were observed by the doctor on his examination. At a later sitting the Board of Control gave further evidence in regard to improvements that might be effected in administration.

IN HONOUR OF DR. BRACKENBURY.

ON the eve of the Insurance Service Conference, which is due to assemble next week, a reception will be held at the Hotel Victoria, London, in order to make a presentation to Dr. Henry Britten Brackenbury, who has almost identified himself with the name and fame of the medical insurance service. In the course of a strenuous professional life, Dr. Brackenbury has found time to take more than a share in the work of the community in which he lives, and in recognition of his service to fellow practitioners he received last July the Gold Medal of Merit of the British Medical Association. As with many others, it was in municipal life that Dr. Brackenbury served his apprenticeship to public office, for he is an alderman of the Metropolitan Borough of Hornsey and has passed the chief magistrate's chair, and he has also presided over the Association of Educational Authorities. We have already quoted the testimonial paid by the chairman of the Court of Inquiry to Dr. Brackenbury's brilliant work in presenting the case of the insurance practitioner, for, he said, "we shall have to steel our hearts against being unduly influenced by his pleadings." Dr. Brackenbury has stated that he desired no better reward than the loyalty and sympathy of his colleagues—which he now possesses in full measure—but those colleagues are well aware both of the financial sacrifice he has made in serving their interest and of the weight which presses on a general practitioner who desires to provide for his own family the educational advantages which he has made possible for others. Along with the gold watch and canteen of silver, intended to be a perpetual reminder of the esteem in which he is held, a cheque for a substantial sum, approaching £6000, will be handed to him. The medical profession is happy in finding at moments of stress and emergency such men as have presided over the Insurance Acts Committee. There have been but two chairmen in the course of its history: Dr. J. A. Macdonald and Dr. Brackenbury, who is only now giving up the chairmanship of the Committee to become President-elect of the Representative Meeting.

THE FOOD INVESTIGATION BOARD.

WHEN the war-time Ministry of Food was finally demobilised, on the grounds that the necessity for its function had passed, its dissolution was looked upon with some misgiving by more than one authority on the subject. Prof. E. H. Starling, at one time scientific adviser to that Ministry of Food, was of the opinion[1] that there should be an inquiry or statistics department which should have knowledge of all food production and consumption, some organisation which could inform the Government as to the value of foods, and supply data and statistics of food consumption and distribution. The fullness of his vision has not yet become reality. Nevertheless valuable work has been done over a period of several years by the Food Investigation Board of the Department of Scientific and Industrial Research in the scientific study of food production and preservation. The Board, whose report for the year 1923–24[2] has just been published, has as its chairman-director Mr. W. B. Hardy, secretary of the Royal Society, and is composed of the following members: Sir Kenneth Anderson, Sir Joseph Broodbank, Sir Alfred Ewing, Sir Walter Fletcher, Sir Richard Threlfall, and Prof. T. B. Wood. The work of the Board is divided up among various committees, each of which deals with some particular branch of the work—namely, engineering, fish preservation, fruit and vegetables, meat preservation, oils and fats, and canned foods. During the past year the most important work carried out by the Board was an investigation into the conditions of the transport of apples from Australia to this country. In 1922 an epidemic of "brown heart"[3] was diagnosed among apples coming from Australia, and this gave rise to the sending of a small scientific expedition to Australia to study the conditions of transport. The ventilation of ships' holds was recognised as a problem of importance, and it was found that excessive ventilation, no less than inadequate ventilation, might be at fault, because the atmosphere surrounding the fruit controls the rate of ripening, and the effect is probably secondary only to that of temperature. Ripening is retarded up to a point more or less proportionately by the presence of carbon dioxide and by a subnormal concentration of oxygen. It is known that it is only in atmospheres containing too much carbon dioxide, over 10 per cent., that the disease of "brown heart" is apt to manifest itself. Starting on these lines, therefore, the whole question of ventilation in ships' holds was investigated from a wide point of view by the members of the expedition, but the special reports of the results have not yet been published. Further work has also been carried out by the Board on the general theory of the freezing of tissues. By studying the freezing of eggs it was found that the state of the yolk, at any rate, might be preserved in two ways without sensible change: either (1) by never allowing the temperature to fall below −6° C., or (2) by freezing and thawing with great rapidity. The report states that it is probable that there is some irreversible change in the nature of a coagulation which occurs at temperatures between −6° C. and an unknown lower limit, which does not occur if this critical interval is hurried over with sufficient rapidity. Laboratory researches have been continued at the Low Temperature Research Station, Cambridge, and at the Imperial College of Science and Technology in London, on such questions as the physiology of fungal infection, the effect of low temperature upon metabolism of apples and upon the parasitism of fungi, and the respiration of potatoes in relation to sugar content.

VOLUNTARY HOSPITALS IN GREAT BRITAIN.

THE fifth annual report[1] of the Joint Red Cross Council on the Voluntary Hospitals in Great Britain (excluding London), which appears as we go to press, is signed by Dr. F. N. K. Menzies, Director of Hospital Services. Dr. Menzies asks for indulgence in view of his inability to take up the late Sir Napier Burnett's work until late in the year. His very notable report analyses the records of over 700 hospitals in England and Scotland with a total expenditure in 1923 of £6,381,115 and total receipts of £7,689,072. In this wonderful year the ordinary income exceeded the ordinary expenditure by over £200,000, and the extraordinary income exceeded the extraordinary expenditure by over £1,000,000. Sixty-seven per cent. of hospitals in England and 62 per cent. of hospitals in Scotland showed a surplus of ordinary income. In these hospitals 770,000 more patients were treated in 1923 than in the previous year, and Dr. Menzies thinks that the time has gone by for the voluntary hospital system to justify itself as a means of relieving sickness and suffering at little or no cost to the public purse, and that the system should boldly claim to carry out this immense volume of work more efficiently and more economically than it could be done by any other known method or system. The charitable public, he is glad to think, is becoming more and more discriminating in the selection of the voluntary institutions which it will support. For himself, he urges the provision of greater facilities for the treatment of such diseases as ophthalmia neonatorum and infantile paralysis, and he exhorts boards of management to acquaint themselves with the particular needs of the area which they serve and to consult the general practitioner as to how they may best assist him in the diagnosis and treatment of his patients. Finally, Dr. Menzies sees great scope for economy in the drug bill of the provincial hospitals of Great Britain, which in 1923 seems to have exceeded £200,000. The report, from which we have taken only one or two salient points, contains a vast amount of material for thoughtful study.

---

[1] Offices of the Council, 19, Berkeley-street, London, W. 1s.

LEEDS CITY COUNCIL'S SUBSIDY TO HOSPITALS.—At a meeting of the Leeds City Council on Oct. 3rd, it was moved and carried that a grant of £10,000 be made to the Leeds General Infirmary, Leeds Public Dispensary, and the Hospital for Women and Children in consideration of an agreement being entered into by each of the committees of these hospitals with the Corporation for the reception by such institutions of the sick inhabitants within the city, the amount to be distributed amongst the hospitals in such proportions as might be decided by the Finance and Parliamentary Committee. There is no question of municipalising the hospitals. At the meeting it was stated that 65 per cent. of the employers of the city were now contributing through the employers' scheme and it appeared only right that the Corporation, as an employer, should contribute. Over 700 Leeds firms are now contributing under the employers' contribution scheme.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XCI.

THE TREATMENT OF POST-MENOPAUSAL HÆMORRHAGE.

BLEEDING from the genital tract after the menopause is so often a symptom of carcinoma that every case met with should be considered malignant unless proved, on careful examination, to be innocent. A heavy responsibility is thus laid on the practitioner who is consulted about such a case, and an awkward situation may arise between him and his patient. It is unjustifiable to treat such cases symptomatically by the administration of ergot or similar drugs. On the one hand, it is unlikely that these drugs will have any beneficial effect; and on the other hand, valuable time may be lost during which a malignant growth may become inoperable.

The Need for a Complete Examination.

When consulted about a case of this kind the practitioner should point out that a pelvic examination is desirable to find out exactly what is wrong; should the patient refuse, he should then state clearly that such bleeding is usually due to early cancer of the womb and that an examination is necessary to determine the point. If the refusal is persisted in, he has cleared himself from future blame and might be justified, in certain circumstances, in refusing to treat the case in ignorance of what is to be treated. The first essential then is a thorough examination to determine the cause of the bleeding.

On abdominal examination a pelvic tumour may be found, but more often is not detectable. In making a pelvic examination it is advisable first of all to examine the vulva in a good light. An unexpected epithelioma of the vulva may be seen, a urethral caruncle, or bleeding hæmorrhoids. Caruncle is not usually a cause of bleeding, but in a certain proportion of elderly patients it will be found associated with carcinoma of the cervix or corpus uteri. When examining the cervix it must be remembered that after the menopause the cervix is small and atrophic, and finally forms a depression rather than a prominence at the vaginal vault. A prominent cervix at this period would be noteworthy, especially if hard and nodular. Another part to be carefully examined is the external os. This may be patulous, and a mucous polyp may be found inside or projecting through the aperture. In other cases the os may be widely dilated, embracing a partially extruded and often degenerating fibromyomatous polypus.

The corpus uteri must now be examined, and here again size and consistency are of the first importance. A post-menopausal uterus is small, and in later life very small, so as to feel almost like a uterus on which subtotal hysterectomy has been performed. Therefore, if the uterus be bulky like an endometritic uterus in early life, and especially if it be definitely hard, the probability of carcinoma of the body is great. If the uterus be enlarged to the size of a cocoanut or more and of a wooden or stony hardness, the chances are more in favour of a fibromyoma, probably undergoing degeneration, it may be malignant degeneration. The fornices must be examined, and any tumour of the appendages carefully noted. Finally, the condition of the heart, lungs, and peripheral vessels should be investigated, and the rectum and bladder examined, the latter by cystoscope if the bleeding appears to originate there.

Lesions Which May be Found.

The various lesions to be described collectively constitute the main causes of post-menopausal bleeding.

On the vulva a patch of epithelioma may be found; pathological conditions of the vagina are rare, and epithelioma, usually extending along the anterior wall from the cervix, is the most common; at the cervix carcinoma is the most common single cause of hæmorrhage, accounting for fully 80 per cent. of all cases. It may be ulcerating or fungating, but more often it is of the atrophic variety. Mucous or fibroid polypi may also be met with here, but such cases must be explored carefully by the curette or finger, as polypi of the cervix are often associated with carcinoma of the corpus uteri. In the corpus uteri, carcinoma or sarcoma are shown by bulkiness and hardness and usually also by a certain degree of fixation; fibromyomata are usually shown by greater size and greater hardness; fibrosis uteri is shown by hardness but little or no increase in size; while in senile endometritis the uterus is only a little enlarged and soft. Carcinoma of a Fallopian tube may be associated with hæmorrhage, but it is a rare condition. Ovarian cysts which are associated with post-climacteric hæmorrhage are to be regarded with suspicion as being probably malignant. From the general point of view, cardiac lesions, chronic renal disease, and high blood pressure may be causative, but only in a very small proportion of cases. Again, in a certain number of cases the most careful examination will detect no physical abnormality anywhere, but such cases are very few.

It cannot be too strongly emphasised that the most probable cause in any individual patient is carcinoma of the cervix or corpus uteri, and this lesion must be presumed until and unless shown to be absent. These considerations will suggest the principles of treatment, which in the great majority of cases is surgical.

Surgical Treatment.

If epithelioma of the vulva or cervix, or carcinoma of the uterus be found, wide removal of the vulval condition, or total hysterectomy, as the case may be, is indicated if the condition be removable. This determination of operability is a most important point which, however, cannot be discussed here. Suffice it to say that while about 60 per cent. of cases of carcinoma of the body of the uterus, and about 30 per cent. of cases of epithelioma of the vulva are removable, it is usual for carcinoma of the cervix to be advanced beyond operation when first seen. This, which is the common experience of all gynæcologists, points the moral of making an early pelvic examination in every case complaining of post-climacteric hæmorrhage. In cases where the vulva, vagina, and cervix are normal the uterus is to be carefully explored by curette or finger. Mucous polypi of the cervix may be removed by forceps or a sharp spoon, but in such case the cervix should always be dilated and the interior of the uterus curetted. The curettings should be microscopically examined for signs of carcinoma. In cases of senile endometritis the curette removes a large amount of broken down débris, often foul, and such cases usually clear up after this operation, which may require to be repeated. In carcinoma of the corpus uteri the cervix is easily—suspiciously easily—dilated, and the material removed by the curette is characteristic. It is of a greyish colour, profuse in amount, soft, cheesy, and often accompanied by bleeding. The curette is to be used gently in order to avoid perforation of the uterus.

In chronic metritis curettage is useful for purposes of diagnosis and exclusion. The amount removed from the uterus is very small or almost nil, and in some cases the hæmorrhage will cease after curettage, but usually it persists. In these cases and also in cases of inoperable carcinoma *radium* is of the greatest value.

Radiotherapy.

In chronic metritis the dosage of radium should be small. A tube of 50 mg. of radium bromide sheathed in platinum is inserted into the cavity of the uterus and left there for eight hours. In about half the cases hæmorrhage ceases after one such application. In the other cases it is either unaffected or improved, and another application should be given after a month's interval. By this treatment quite 75 per cent. of simple hæmorrhages from the uterus can be controlled. In the cases which do not react favourably, hysterectomy is the only choice left open. In inoperable carcinoma or sarcoma of the body of the uterus 100 to 120 mg. should be introduced into the uterine cavity for 24 hours. The effect of this is usually most beneficial and the hæmorrhage ceases, the discharge disappears, and the patient's general condition improves. Should the bleeding recur, the treatment can be repeated; again, the local conditions may so improve that a patient at first considered inoperable can later be operated on with safety. In inoperable carcinoma of the cervix it is a matter of personal opinion as to whether any fungating or ulcerating condition should be curetted before radium is applied. The cervix should be steadied with a volsellum, if it is possible to catch it without tearing, and two tubes of 50 mg. of radium each are introduced into the cervical canal. Several other smaller tubes are inserted into the peripheral parts of the growth, giving a dose of 170 mg. in all, which should be left in for 24 hours. The effect of this is usually most satisfactory, the bleeding and discharge ceasing within a week or two, and the local condition usually healing up almost beyond recognition. Such patients have to be watched from time to time, and it is well to repeat the application after four weeks. In vulval epithelioma the results of radium therapy are disappointing.

Fibromyomata of the uterus should be removed by appropriate means. This usually involves hysterectomy, but a pedunculated polyp may be removed per vaginam by avulsion or cutting with scissors or, if the condition be larger and degenerating, by morcellement. If sloughing and pedunculated, laparotomy is to be avoided if at all possible on account of the grave risk of peritonitis. In some cases vaginal hysterectomy is indicated, but the abdominal route is more often chosen to-day. Ovariotomy or salpingo-oöphorectomy is called for where an ovarian cyst or tubal disease is present, and in these cases it is better to remove the uterus at the same time. A urethral caruncle can be removed most easily by the actual cautery at a dull red heat and using a fine point. With the patient in the lithotomy position the caruncle is gently pulled on with forceps and the cautery point passed through the urethral mucosa at its base. If general anæsthesia be undesirable, local infiltration with novocaine and adrenalin does very well.

Drugs do not require discussion, because in bleeding of the type under consideration ergot, pituitrin, adrenalin, and such preparations are generally found to be of no value, as would, indeed, be judged probable from a consideration of the causes of the bleeding. Almost always the bleeding has a local cause and requires local treatment.

Conclusion.

It will be evident from what has been said that post-menopausal hæmorrhage as a rule indicates a serious, and it may be a fatal, condition. Treatment is usually operative and may involve a major operation, and it is on that account that a thorough pelvic examination should be made as soon as possible, in order that appropriate treatment may be instituted at a time when it may benefit the patient.

GILBERT I. STRACHAN, M.D. Glasg.,
M.R.C.P. Lond., F.R.C.S. Eng.,
Assistant Gynæcologist to the Cardiff Royal Infirmary.

Messrs. William Hodge and Co., Ltd., announce for early publication two further volumes in the Notable British Trials series. The first will deal with the well-known case of Adolf Beck and is edited by Mr. Eric Watson. The second will deal with Henry Fauntleroy, the banker, who was tried for forgery and executed in 1824, and is edited by Mr. Horace Bleackley.

THE WORKING OF THE INSURANCE MEDICAL SERVICE.

WITH the end of 1923 the Insurance Medical Service completed the eleventh year of its existence. In the annual report[1] Sir George Newman states, and with some justification, that the inception of this service in 1913 was one of the most important events in the history of British public health progress, for which the establishment of the insurance doctor the State assumed large responsibilities for the medical treatment of practically the whole of the wage-earners of the country. The Insurance Medical Service follows closely the lines of private general practice. State control and State interference are reduced to the minimum that is compatible with due recognition of public responsibility, and one of the chief aims of the service is to preserve that intimate relation of doctor and patient which finds expression in the phrase "the family doctor." It has been made a reproach against the Insurance Medical Service that it provides nothing more than the services of general practitioners. It is true that the service would work with much greater effect if coördinated with a comprehensive scheme of consultant services. Such a scheme was devised in 1914, and the necessary funds were voted by Parliament; but the project foundered in the great catastrophe of the war.

General Work of the Medical Practitioner.

There is danger that the value of the general practitioners' work may be overlooked. Though it avoids publicity, and meets with scant public recognition, its public importance and utility are immense. The general practitioner forms our first line of attack in the fight against disease and premature death. His skill must be the sieve that distinguishes the important from the unimportant, and if he is worthily to play his part it is essential that he should be familiar with the beginnings of disease, for it is in its beginnings that disease can be most successfully controlled. Early recognition is equally important from the point of view of the patient. It would be too much to expect the general practitioner to make a confident diagnosis in every case; but he will, if ordinarily well-equipped, be able to select those cases in which he should seek specially skilled assistance to enable him to arrive at a right view of the case. To this end it is essential that the general practitioner should be closely in touch with the workers in his area who are engaged in other fields of medical work. There are many and various agencies, both voluntary and State-aided, for the control of disease, and they would all work with greatly enhanced effect if coördinated as parts of a complete scheme of medical services. The precise reciprocal relation of each agency to the others needs to be carefully thought out, clearly defined, and brought into effective operation. The framing of such a scheme is a matter of considerable difficulty, but Sir George Newman says it has long been overdue, and the benefit to the country of the establishment of such a comprehensive coördinated system would be immense. The expenditure of labour and money which each of the various health agencies already puts forth year by year is, it is true, enormous; but for lack of proper coördination the highest possible return for such expenditure is not attained.

Particular Work of the Insurance Practitioner.

As a general practitioner, the insurance doctor has the important advantage that, through the absence of any financial deterrent, his insured patients consult him earlier and more frequently than do his private patients. Medical attendances shown by the record cards to be given to insured persons are about three times as numerous as those stated in the Plender report to have been given in private practice per head of the population. The general practitioner has, therefore, much greater opportunities in insurance practice than in private practice of seeing those illnesses, trivial perhaps at initiation, which constitute the beginnings of serious disease, and is also more favourably placed for close observation of the course of an illness in an insured patient than in most private patients. His special relation to the State involves also the fulfilment of functions of peculiar importance to the community, three of which are thus briefly set out in the report:—

---

[1] On the State of the Public Health. Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1923. 3s.

1. *Incapacity Certification.*—Not only have insurance doctors to secure the speediest possible termination of the wage-earners' sickness, but they have also the important duty of determining whether their patients are, or are not, incapable of work, and of giving, or refusing, medical certificates of incapacity in accordance with their opinion in each case. Every year in England and Wales over 11 million pounds are expended in sickness and disablement benefit to insured persons who are incapable of work, and in nearly every case the chief evidence, in many cases practically the only evidence, of incapacity is the certificate of the insurance doctor. It is doubtful whether the importance of this side of the insurance doctor's work is sufficiently appreciated. Its difficulties are great, for the question whether a patient is incapable of work is not one that can be determined by the routine application of general rules.

2. *Advancement of Medical Knowledge.* — The incapacity certificates of the insurance practitioners afford an immense mass of statistical material relating to those insured persons whose sickness has reached the point of causing incapacity for work; and in the medical records kept by insurance practitioners, in respect of the illnesses of all patients attended by them, whether incapacitated or not, there is a greater mass of material available for statistical examination, adding to our knowledge of the incidence of disease and its results. Further, the insurance doctor, in addition to furnishing the data so far mentioned, which emerge in the routine course of his daily work, is exceptionally well placed for participating in special inquiries into various problems of disease prevalence, of which the recent inquiry of the Rheumatism Committee of the Ministry is an instructive example. The report of the Committee is largely based on observations on their insured patients made by 49 insurance practitioners working in coöperation with medical officers of the Ministry.[2] The number of insured persons on each practitioner's list being known, the total population at risk was estimated with sufficient accuracy; and thus it was possible to obtain information of the incidence of rheumatism on a population of 90,000 persons, which was regarded as a sufficiently large and varied group to form a reasonable sample of the total insured persons in England and Wales. The report of this inquiry clearly shows the opportunities opened up to the insurance practitioner in elucidating some of the most baffling of the problems of disease.

3. *Public Education in Hygiene.*—The special relation of the insurance practitioner to his insured patients is of exceptional importance, as affording him opportunity as an educator in health. The obstacle of the fee is not interposed between the insured person and the doctor of his choice. The insured patient can consult his doctor at the first onset of disquieting symptoms. The deterrent effect of the doctor's bill does not exist for him; and his doctor is not a stranger, but an adviser, who is freely chosen by him, and may have attended him for years. Hence the insured person goes to his doctor early and often. Many of his patients are young, for employed persons come into insurance at 16 years of age, and the insurance doctor, going as he does freely into the homes of his patients, and knowing their home conditions, is well able to advise on the healthy ordering of the home, the formation of healthy personal habits, hygienic diets, suitable occupations, and other measures tending to "keep the doctor away." It is on such activities, says Sir George Newman, rather than on the prescribing of innumerable bottles of medicine that we must base our hopes for further progress towards the realisation of our health ideals.

The Work of the Year.

With regard to the actual work carried out under the Insurance Medical Service during the year 1923, the following statements of particulars will be of interest. Though it will be understood that the value of the service cannot be expressed in terms of statistics, some idea of the magnitude of its work may be formed from these facts and figures.

Insured persons can obtain medical treatment under the provisions of the Insurance Acts by one of three methods. (i.) By far the most usual method is for the insured person to place himself under the medical care of a practitioner who has accepted the conditions of the insurance service and whose name is included in the Medical List of such practitioners prepared by the insurance committee of the area. (ii.) He may elect to obtain treatment from a medical aid institution existing at the time of the passing of the National Insurance Act, 1911, which has been approved by the Insurance Committee and the Insurance Commissioners under Section 15 (4) of that Act; or (iii.) he may with the consent of the local insurance committee make his own arrangements for medical attendance, receiving from the committee a contribution towards the cost of such treatment.

The following table shows to what extent these various methods are selected by the insured population. In 1923 the number of insured persons entitled to medical benefit under the Insurance Acts was (approximately) in England 12,487,000, and in Wales 833,000, making a total of 13,320,000. The approximate number of insured persons who had elected to obtain treatment by each of the methods described is given below:—

—	No. of insured persons.		
	On lists of insurance practitioners.	On lists of approved institutions.	Making their own arrangements.
England	12,000,000	130,000	29,000
Wales	749,000	31,000	7,500
Total ..	12,749,000	161,000	36,500

The number of insurance practitioners in 1923 was in England 12,000, and in Wales 855, a total of 12,855. The average number of insured persons on a doctor's list was 992.

Some Misconceptions.—It may be useful in this connexion to mention two rather widely-spread misconceptions of the work of the Insurance Medical Service. One is that there is a great number of insurance doctors with excessively large and unwieldy lists. The fact is that only 2·1 per cent. of the doctors have a list of over 3000 persons, and in no such case does the doctor work single-handed. The total number of doctors having 2000 or more insured persons on their respective lists is under 14 per cent. of the total number of insurance doctors, and many of these employ assistants. Under the old regulations the maximum number of insured persons on the list of a doctor working without a partner or assistant was 3000, and this maximum has been reduced to 2500 by the regulations that came into operation on Jan. 1st, 1924; and in any area this maximum may be still further reduced by the Insurance Committee in agreement with the Panel Committee. More than one-half of the insurance practitioners have less than 1000 persons per doctor's list.

---

[2] Reports on Public Health and Medical Subjects, No. 23, The Incidence of Rheumatic Diseases, 1924.

Another misconception is prevalent as to the amount of work falling upon a doctor with a list of a given size. On this point valuable information was collected in an examination made of the medical records of a large number of representative practices by the Regional Medical Staff in the summer of 1923. The records of the practices showed that the visits and attendances made during 1922, due allowance being made in respect of persons who died or lapsed from insurance during the year, were equivalent to 3·5 per person on a doctor's list, whether well or sick; and thus a doctor having 2000 persons on his list would, assuming 300 working days in the year, make on an average about 7000 visits and surgery attendances during the year, or about 8 visits and 16 attendances per working day.

Arrangements with Chemists.—Insured persons normally obtain their medicines and appliances from chemists on a doctor's prescription, but in country areas where no chemist is available the doctor on whose list the insured person's name is placed supplies medicines and appliances. The insured person has a free choice of chemist as well as doctor. He is perfectly free to take any given prescription to any chemist whose name is on the list of insurance chemists of the area. The number of chemists' shops available for the supply of medicines and appliances to insured persons in 1923 was in England 8500, and in Wales 626, total 9126. The total number of prescriptions dispensed was, approximately, in England 36,000,000, and in Wales 2,000,000, total 38,000,000. The estimated cost of medicines and appliances supplied was, approximately, in England £1,430,000, and in Wales £86,000, total £1,516,000.

Additional Benefits of Approved Societies.—Approved societies having a disposable surplus at the first valuation, which was made as at Dec. 31st, 1918, can, besides administering the ordinary cash benefits,—namely, sickness, disablement, and maternity benefits—devote the whole or part of their disposable surplus to the provision of certain additional benefits specified in the National Health Insurance Acts. The additional benefits at present available are administered by approved societies under the general supervision of the Ministry and have no direct relation to the Insurance Medical Service, except that an insurance practitioner who has advised a patient to obtain special treatment, payment for which is made by his society as an additional benefit, is under an obligation, if so requested by the patient, to include in his next medical certificate a statement of the form of treatment so advised. Over 1000 societies and branches have adopted schemes which include what are designated "treatment benefits," these taking the form of contributions by the societies for defraying the whole or part of the cost of some form of special medical or dental treatment obtained by their members. The most popular of the "treatment benefits" is dental benefit, which may comprise the provision of dentures as well as defraying the cost of dental treatment. Other benefits take the form of payments for optical treatment and glasses, or for the supply and repair of artificial limbs or appliances, such as crutches, surgical boots, and trusses. Nearly £300,000 was available in the year 1923 for payments to hospitals or convalescent homes in respect of in-patient treatment, and some societies maintain convalescent homes of their own. The total amount actually expended in the year 1923 on the provision of additional benefits was about £500,000.

The Regional Medical Staff.

The end of the year 1923 marked the completion of the third year of the work of the Regional Medical Staff, which was initiated in the latter part of 1920. The staff, which consists at present of 31 regional medical officers and five divisional medical officers, was appointed with a dual object. First, it was desired to make available to doctors and societies alike the opinion of a medical referee in cases of doubtful incapacity for work, and also in cases of admitted incapacity in which a second medical opinion was thought likely to lead to the restoration of the patient's capacity for work. But, secondly, the view was also held, and it was a view that was soon amply confirmed by experience, that the existence in the main centres of population of a body of senior medical men of long experience in industrial practice would afford the department special opportunities for carrying out work of considerable public health importance which otherwise could not have been accomplished except at material disadvantage. The number of cases of doubtful incapacity for work referred to the staff during the year was 146,381, as against 113,685 in the previous year, an increase of 29 per cent. Of the total 146,381 cases, 144,556 were referred by approved societies, 542 by insurance committees, and 1283 by practitioners. The total number of persons referred who were examined during 1923 was 85,773, and of these, 63,402 were found to be incapable and 22,371 not incapable of work. An additional 60,261 persons referred for examination declared off the funds, or for some other reason failed to present themselves for examination. There were also 2802 "consultation" cases referred, 2344 by societies, 452 by practitioners, and 6 by insurance committees, the number examined being 1985. The total number of incapacity and consultation cases referred during the year was 149,183, and the number of cases in which an examination was made was 87,758. In addition, the staff examined at the request of the Ministry of Labour 31 pensioners in regard to whom doubt was felt whether they were fit to attend for training; and examinations were made on 432 persons claiming pensions under the Blind Persons Act, 1920, on the ground that they were so blind as to be unable to perform work for which eyesight is essential.

Several special investigations were undertaken by the staff during the year. Special inquiries were made into disease prevalence, and into various administrative questions arising in connexion with the Insurance Medical Service.

Inspection of Insurance Medical Records.—Insurance practitioners have the duty of keeping records of the illness of their insured patients. The record is a document of considerable clinical importance, since it is in a permanent form and passes from one doctor to the other with every change of doctor made by the patient. Obviously, there must be some system of supervision of the keeping of documents so important; and from the first it was clear that such supervision could best be undertaken by the regional medical officers, who, in their work as medical referees, are necessarily brought into close relation with the practitioners of each area. The number of visits made by the staff for purposes of record inspection during 1923 was 5903, and the improvement in the methods of record-keeping was found to be maintained during last year. Much useful work was done by the staff in showing how the records could best be kept in such a way as to derive full benefit from their use while observing due economy of the time of a busy practitioner. In a small number of cases the counsel of the regional medical officer failed to secure a proper standard of record-keeping, and the facts were reported to the Minister for further action.

Inspection of Dangerous Drugs Records.—Insurance practitioners who dispense medicines are subject, like all dispensing doctors, to the requirement, imposed by the regulations made under the Dangerous Drugs Acts, to keep records of their purchases and supplies of the drugs to which those Acts apply. By arrangement between the Ministry and the Home Office, such records, whether kept by insurance or non-insurance doctors, are inspected by the Regional Medical Staff, and during 1923 there were 4401 visits of inspection made for this purpose. In addition to the routine inspections some 20 visits were made at the request of the Home Office to doctors who appeared to be prescribing or dispensing the drugs for purposes other than that of medical treatment. In each case the provisions of the Acts applying to medical practitioners were fully explained to the doctor, and a special report made on the case for transmission to the Home Office. Hospitals are also required under the Acts to keep records, which are inspected by the staff, who, during the year, made 112 visits of inspection.

Sir George Newman states, however, that the value of the work of the Regional Medical Staff cannot be estimated from a mere recital of the number of inspections and examinations made annually. Its chief value, he considers, lies perhaps in its indirect influence upon the Insurance Medical Service, as the work of the practitioners cannot but be affected by the knowledge that their methods of practice come under the review of a senior colleague, who from his own experience as a general practitioner is well aware of the circumstances that make for a high standard of professional work.

NATIONAL HEALTH INSURANCE UNDER THE WELSH BOARD OF HEALTH.[3]

The conditions during the year were on the whole more favourable from the approved society point of view than in the previous year, in that unemployment, though still general, was less severe, and benefit claims were less numerous. Many societies, however, found their disablement benefit claims very heavy. Special arrangements were again made to credit members who were unemployed for prolonged periods with sufficient contributions to maintain their title to benefits.

The standard of administration in the case both of societies and of branches showed a substantial improvement. The department continued to review closely the administration of all units, particular attention being paid to cases in which the audit reports revealed weaknesses, or complaints were made by members. Furthermore, steps were taken to render assistance and guidance to all newly appointed secretaries. Evidence is not wanting that secretaries generally are more alive than formerly to the importance of keeping their records up to date, and of administering the various benefits promptly and efficiently. The adverse industrial conditions prevailing, with the consequent unemployment and distress, have also resulted in better appreciation and understanding of the provisions and requirements of the Acts generally.

Deposit Contributors.

The membership of the Deposit Contributors Fund now remains fairly constant at about 10,500. It is observed that about 5500 new accounts are opened annually, whilst about the same number of persons annually cease to be deposit contributors by reason of transfer to approved societies, lapses from insurance, emigration, death, &c.

The efforts made to bring to the notice of deposit contributors the advantages of approved society membership have been continued throughout the year. The number of effective applications received during the year for transfer to societies was 3640. It is hoped, however, Mr. Wheatley states, that the additional benefit schemes adopted by societies, consequent on valuation results, will appeal to a larger number of deposit contributors. So far there has been no marked effect in this direction, and experience has shown that the contributor, as a rule, remains somewhat indifferent to his insurance position until the question of cessation of benefit arises owing to the exhaustion of his credit. During 1923 over 500 payments of benefit ceased by reason of exhausted credits.

MEDICINE AND THE LAW.

THE CHARGE AGAINST DR. HADWEN.

THE Gloucester City Bench recently committed Dr. W. R. Hadwen for trial at the next assizes on a charge of manslaughter, arising out of the death of Nellie Burnham, 10½ years of age, the daughter of a steel presser. Dr. Hadwen had already been similarly committed on a coroner's inquisition in respect of the same death,[1] the allegation being that the child died of diphtheria, and that he was guilty of negligence in treating her. The evidence before the magistrates was mainly that of witnesses called at the inquest, with the addition of Sir William H. Willcox. Mrs. Burnham, mother of the deceased, stated that in washing the child's clothing after her death she found in the bath "a piece of substance like chewed tissue-paper," yellow and similar to the substance she had seen in the throat of her child. She admitted not having told the coroner of this, as it had "slipped her memory" when in the witness-box, and it was not until she heard the medical witnesses at the inquest giving evidence as to the membrane that she realised it was something important, otherwise "she would have spoken about it at the time." Dr. E. S. Ellis, who was called in before the child died and refused to give a certificate, as he had not "attended her in her last illness," repeated his evidence and was cross-examined as to a correspondence which he had had with Dr. Hadwen arising out of the recent epidemic of small-pox. Dr. Ellis admitted having at that time resented an attack made by Dr. Hadwen upon the medical profession in an advertisement inserted by him in a local newspaper. He said, however, that an arrangement had been made with regard to this controversy, that he was a member of committees with Dr. Hadwen, and though he was not on speaking terms with him at the time referred to in his evidence, Dr. Ellis denied that he had "any animus whatever" against Dr. Hadwen. Sir William Willcox gave expert evidence as to the symptoms of diphtheria and its detection, particularly with regard to the desirability of taking a swab. With reference to Dr. Hadwen's treatment of the deceased, he said that it was not proper treatment, that he did not think that if Dr. Hadwen had made a careful examination he could have failed to notice symptoms indicating diphtheria "unmistakably." In reply to a question, he answered: "I think if proper treatment had been given the first day there is reasonable probability that the child's life would have been saved."

An interesting question of the limits and admissibility of expert evidence arose when Sir William Willcox was asked by Mr. St. John Micklethwait, counsel for the prosecution, whether the patient's death was caused or accelerated by Dr. Hadwen's failure. Mr. A. F. Clements, for Dr. Hadwen, objected to this as tantamount to asking whether Dr. Hadwen had committed manslaughter. The magistrates held that the witness as an expert was entitled to express an opinion as asked, and Sir William Willcox answered: "In my opinion, in all reasonable probability it was." As to the possibility of the child having contracted pneumonia by going downstairs to get water, he was of opinion that it was possible but extremely unlikely. Sir William Willcox had no doubt that the case was one of diphtheria, and added that even if Dr. Hadwen doubted it, there was no justification for his not taking a swab. After counsel had submitted that there was no case on which a jury could convict of manslaughter, the magistrates retired to consult, and on their return to court announced their decision as stated above.

QUERY DRUNK.

Mr. H. W. Wilberforce, at Marylebone police-court, recently sentenced to 21 days' imprisonment T. F. Goode, a mechanic, and suspended his licence for six months, on a charge of being drunk while driving a motor van. The man had admitted having had two glasses of beer and some whisky, and Dr. C. J. R. McFadden, who gave evidence in his capacity of police surgeon, certified that Goode was suffering from the effects of alcohol when he saw him, and said that he was not sober, and was not fit to be in charge of a vehicle. This did not satisfy the magistrate, who pressed the medical witness to say definitely whether the man was, or was not, "drunk." To this he received the reply that the question put in this way was a very difficult one to answer. "He was in a certain degree drunk," said the witness. On this the magistrate accused Dr. McFadden of trying to "wriggle out" of giving a definite answer to the question, and obtained finally the reply that Goode was "suffering from drunkenness." "Well, he was drunk," said Mr. Wilberforce, and inflicted penalties as above stated, after making the further comment that medical men preferred to make their own definitions and resented the attempts of other people to get answers in a form which they (the doctors) did not approve.

---

[3] From the Fifth Annual Report of the Ministry of Health, 1923–24. London: H.M. Stationery Office. 5*s.*

[1] THE LANCET, Sept. 20th, p. 626.

In comment it is to be observed that a medical witness endeavouring to express himself with accuracy and without any unfairness to the accused person cannot justly be described as "wriggling" because he prefers to say that a man is suffering from the effects of alcohol and unfit to drive a motor car, rather than to describe him baldly as "drunk." And it is of interest to all medical men liable to be called on such occasions to know exactly what the law expects of them. This is not very easy to state, if Mr. Wilberforce and any other magistrate who agrees with him are right. "Drunk" is a more or less popular term of an elastic nature. Murray's English dictionary defines as drunk a man "that has drunk intoxicating liquor to an extent that affects steady self-control; intoxicated, inebriated, overcome by alcoholic liquor." To this is added, "the degree of inebriation is expressed by various adjectives and adverbs, as 'beastly,' 'blind,' 'dead,' 'half,' &c." Later on the same authority quotes from Swift an eloquent but not very definite illustration of more or less extreme intoxication. "He came to us as drunk as David's sow." "Drunk" is not a medical term, and it is submitted that in the case of motorists it is the function of the magistrate to find as a fact whether the accused person was drunk when in charge of a motor car, that is to say, too much under the influence of alcohol for it to be safe for him to drive it, and that the magistrate in so doing has to base his finding on the evidence of witnesses, of whom the doctor can only depose to, and draw inferences from, the man's condition when he saw him, this being in most cases some little time after arrest by the police.

The essential point in cases such as the above would appear to be whether the man was unfitted by liquor for driving a motor car on a highway with reasonable care for the safety of others, and with the capacity to arrive quickly and accurately at correct decisions in the emergencies inseparable from such a task. The definition of drunkenness as a condition affecting steady self-control appears to cover this very fairly, but the general application of the term "drunk" goes rather further, and a witness may wish to know how the word is interpreted by the questioner in the circumstances in which the question is put. The popular conception of "drunk" comes nearer to "overcome by alcoholic liquor" or "as drunk as David's sow," and probably Dr. McFadden had this in view when Mr. Wilberforce thought that he "wriggled" in the witness-box.

YORKSHIRE TUBERCULOSIS SOCIETY.—On Saturday, Oct. 25th, at 4 P.M., at the Tuberculosis Dispensary, Queen's-road, Sheffield, Mr. Morriston Davies will lecture, with lantern illustrations, to the Society on Surgery in the Treatment of Pulmonary uberculosis. All medical practitioners are welcome.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.

POST-GRADUATE COURSE.

THE week-end post-graduate course at St. Mary's Hospital was established two years ago, and the 11 meetings held from Oct. 4th to 6th proved as popular to medical men and women as those of the preceding years. The attendances at each lecture and demonstration numbered from 80 to 150.

On Oct. 4th the first lecture was delivered by Mr. T. G. Stevens, the subject being

Chronic Metritis and Allied Disorders.

Mr. Stevens said that chronic metritis or, as it was formerly called, fibrosis uteri, was the name given to a condition of hypertrophy of the uterine muscle and connective tissue associated with an elastic tissue replacement of the muscle coats of the branches of the uterine artery. In 95 per cent. of the cases the condition was the result of pregnancy and subinvolution, quite frequently only one pregnancy having occurred. Pregnancy was invariably attended by an increase in the elastic tissue in the arterial coats, but when subinvolution occurred the increase of elastic tissue was enormous and very largely replaced the muscle coats, so that the blood-vessels no longer were able to contract and control the amount of blood flowing through them. The very great thickness of the uterine wall which was found invariably in chronic metritis was due partly to a persistence of the increased muscle and fibrous hypertrophy of pregnancy, but much more to an actual post-puerperal hypertrophy of these tissues. Formerly it was thought that this increased thickness was due to fibrous tissue overgrowth only; this was now known to be erroneous, as the fibrous and muscular tissue occurred in chronic metritis in their usual relative proportions. The cause of this hypertrophy was probably the result of the loss of control in the uterine arteries owing to their degenerate walls. When the vessels could no longer control the circulation the uterine muscle, by its contractile efforts, attempted to keep up this control, and in these unusual efforts gradually hypertrophied. Circulatory control was moderately good for a time, but as there was a limit beyond which hypertrophy could not go, after a time the circulatory control broke down. The result was chronic over-filling of the distensible uterine vessels and subsequent excessive hæmorrhage at menstruation. This blood loss was not only excessive, but prolonged, often lasting many weeks, the normal mechanism by which menstrual hæmorrhage was stopped being feeble or in abeyance. Chronic metritis only caused excessive *menstrual* loss; once the menopause had occurred, chronic metritis never caused hæmorrhage and ceased to be of any importance. Usually the menorrhagia of chronic metritis began after the age of 40, or even later as the time of the menopause approached. In a minor degree, however, this symptom might occur in younger women. Chronic metritis was one of the common affections causing prolonged hæmorrhage at or about the menopause, and consequently must be diagnosed from carcinoma of the cervix, carcinoma of the body of the uterus, submucous fibroids, fibroid polypi, mucous polypi, &c. Apart from cancer of the cervix and obvious polypi, the diagnosis could not be made except by dilatation and exploratory curettage of the uterus, especially to exclude carcinoma of the body of the uterus. As the endometrium was usually not thickened in the subinvolution type of chronic metritis, the curette brought away practically nothing, whereas in the so-called endometritis gelatinous strips of thickened mucosa were removed, and in carcinoma cheesy masses were obtained. Once the diagnosis of chronic metritis was made the choice of treatment lay between radium, X rays, and hysterectomy. Radium applied *inside* the uterus after dilatation would usually bring about a cessation of menstruation and consequently cure the one important symptom, but it left an unhealthy organ, and time alone would show whether there was any increased liability to carcinoma in a uterus thus treated. X rays would bring about the same result, but the treatment was more irksome than a single radium application. Hysterectomy was the ideal treatment as it removed the unhealthy organ, and was especially indicated in cases where chronic metritis was complicated by old lacerations and hypertrophy of the cervix. Hysterectomy carried out by the vaginal route for chronic metritis was an extremely satisfactory operation, attended by few of the discomforts of an abdominal operation and by a mortality which was smaller than that of abdominal hysterectomy was ever likely to be.

Sir William Willcox then gave a discourse on the

Toxic Factor in Disease.

He said that the paramount importance of toxæmia in diseases where the organism causing the disease was known would not be disputed. For example, in the septicæmias of streptococcal or staphylococcal origin, in the typhoid group of diseases, in pneumonia, &c., the causal organism could be readily isolated from the blood and undoubtedly produced the toxic effects present. Other examples were diphtheria, tuberculosis, and the protozoal diseases such as malaria and including syphilis. A large number of diseases were met with in medical practice the exact causation of which was less clearly known. These diseases formed the bulk of the "common ailments." The evidence of recent medical research pointed most strongly to a toxic factor as being the chief, if not the sole, cause of many of these diseases. For example, the various manifestations of fibrositis in which should be included the different types of arthritis, the various forms of perineuritis such as sciatica, brachial neuritis, &c., inflammatory conditions of aponeuroses (muscular rheumatism), tendons, and ligaments were due undoubtedly to a toxic cause. The toxic factor in disease, he said, was probably more appreciated in this country than in any other, and this was largely due to the work of Sir Almroth Wright and his co-workers.

In discussing the cause of the toxæmia, the lecturer said that in most cases a local focus of infection could be found, and the great importance of searching for it could not be too strongly urged. The teeth should be examined clinically and also by means of X rays. Often apical periodontal disease was present when to the naked eye the teeth appeared healthy. The tonsils, naso-pharynx, antra, and accessory sinuses should be submitted to expert examination and if necessary to radiographic examinations. The colon should be submitted to a bacterial examination of its washings, and the urine bacteriologically examined. The treatment of the disease should commence with the treatment of the local focus of infection, and where possible, as in the case of infected teeth, tonsils, or antra, this should be dealt with by surgical measures. Vaccine therapy was only of value when the local focus of infection had been eradicated or adequately treated. Secondary infections from an original primary focus must always be borne in mind. For example, arthritis might result from dental sepsis or infected tonsils, and unless these primary foci were dealt with early, a secondary infection of the colon was very likely to occur. A secondary infection rendered the treatment of the toxic factor more difficult.

Sensitisation to idiopathic protein poisons was well known, as, for example, the susceptibility of certain persons to minute doses of pollen protein in hay fever. There appeared to be little doubt but that sensitisation to a bacterial poison was the cause of certain common diseases. For example, asthma might be caused by bacterial infections of the naso-pharynx or respiratory tract. Gout in some cases was caused by the bacterial infection arising from teeth or bowel. In cases where the disease was due to sensitisation to a bacterial poison, it was of prime importance that any focus of infection should be dealt with, and if this could be removed or adequately treated improvement was sure to follow. Vaccine treatment in cases of sensitisation was often contra-indicated, and if used only very minute doses should be cautiously given. In the examination and treatment of diseases the exact cause of which was unknown, it was certain that a toxic factor could in most cases be looked for with great hope of success, and when found the line of successful treatment was clearly indicated.

Colonic Toxæmia and its Medical Treatment.

Dr. REGINALD MILLER defined colonic toxæmia as a condition of ill-health arising from the absorption of poison from the lower bowel in persons who showed no gross intestinal disease. He regarded the term "intestinal stasis" for this disorder as an unhappy one in that stasis might exist without toxæmia and toxæmia without stasis. No merely mechanical explanation was satisfactory, and the essential factor to be considered was the state of the bowel wall. Where the colon remained healthy no absorption occurred, but where the wall of the colon became inflamed its impermeability was lost and ill-health resulted. The catarrh of the colon in some cases resulted from an acute infection or food-poisoning, but in the majority of cases it was set up by prolonged constipation. In these it was probable that fæcal decomposition occurred, producing irritant poisons which inflamed the wall of the colon. The symptoms of the complaint were numerous and often overshadowed by the general picture of neurasthenia. The symptoms of colonic discomfort had to be carefully appreciated and their characteristics were described. The stools were usually either hard and constipated or liquid and foul. They did not always contain obvious mucus until the bowel was washed out. Gastric symptoms might be superadded. Very little help was obtained from bacteriology; the most frequent alteration was a diminution in the numbers of *B. coli* and an increase in streptococci. There was no evidence in the majority of cases of an infection being at work. In addition to the abdominal symptoms there was a rather characteristic fatigue, physical and mental, associated with headaches, nervous symptoms, muscular pains, especially "lumbago."

The chief factor in the treatment of all but the mildest cases was by means of Plombières douches for the colon. It was, unfortunately, not true that anyone could give this treatment correctly, nor was it easy to give it at home or even in nursing homes. The secret of it was the high and even pressure with which the Plombières water was introduced. A course of 8 or 12 treatments was generally necessary, but improvement was usually quickly observed. The question of aperients was a difficult one, but a great step forward had been taken since the introduction of preparations of bile, such as "Taxol" tablets. These did not produce any irritation of the colon, and the stool resulting from their use was formed instead of the more toxic liquid variety. The use of small injections of cold olive oil was most valuable in cases of great tenderness or severe constipation. Diet and rest had also to be considered.

Dr. A. Hope Gosse spoke on

Common Cardiac Irregularities.

He said that while graphic methods had made the diagnosis of cardiac irregularities more exact, these methods could frequently be omitted without sacrifice to the precision of diagnosis. He then dealt in some detail with various types of irregularity. *Sinus arrhythmia* was the youthful type of irregularity and tended to disappear in adults. The pulse-rate was slow and the rhythm faster with inspiration, slowing down with expiration; while the breath was held the rhythm was regular. This condition was observed during convalescence after acute infections when the pulse was slow. *Premature contractions* represented the commonest type of irregularity in adults, and might be called the adult type of irregularity. The rhythm varied from minute to minute, hour to hour, and day to day. Irregular beat occurred: (*a*) every alternate beat, (*b*) every fourth or eighth beat, (*c*) as an isolated beat, (*d*) with varying frequency. Premature contractions increased in frequency with increasing age. With the finger one might detect a small beat at the wrist or there was an apparent pause, while with the stethoscope the first and second sounds of premature beat were heard at the apex. Exercise diminished the irregularity by quickening the pulse-rate. The condition was attributable to errors of digestion, excess of tobacco or alcohol, or toxic causes, and its presence or absence in a patient did not affect prognosis. *Auricular fibrillation* was the commonest form of severe heart disease. Here the pulse was continuously irregular, and exercise exaggerated the irregularity by quickening the pulse-rate. The size of the beat varied without much relation to length of the preceding pause, nor was there any relation to respiration. When the rate was very rapid many beats (even 30 or 40 per minute) were imperceptible at the wrists, but this error could be avoided by counting by auscultation. If mitral stenosis was also present the murmur at the apex was diastolic in time. The heart was increased in size. The modes of onset of auricular fibrillation were as follows: (*a*) premature contractions might precede; (*b*) a single paroxysm followed by years of regular rhythm; (*c*) frequent paroxysms and of varying duration; (*d*) auricular flutter might precede; (*e*) first attack might persist for life. The prognosis depended on the response to effort, on the size of the heart, presence or absence of valvular disease, on pulse-rate, and on the amount of digitalis required to control the rate. Treatment consisted in rest and quinidine in the early stages, followed by rest and digitalis in the later stages. *Auricular flutter* was much less common than fibrillation and comparatively unstable. In this condition the normal rhythm returned or fibrillation developed. The auricular rate was about 320 per minute with a ventricular rate half or a quarter of this. When the patient is recumbent the raising of one limb might double the ventricular rate. There was no respiratory variation in rhythm, and the rate never gradually slowed down. Digitalis frequently changed this rhythm into fibrillation and later to a normal rhythm. The treatment was similar to that for fibrillation. *Heart-block* could be divided into three degrees: (*a*) delayed conductivity, (*b*) with dropped beats, (*c*) complete. All degrees were met with in the acute and chronic form. The degree (*a*) could only be recognised clinically by a mid-diastolic murmur at apex due to mitral stenosis, while the degree (*b*) could be recognised by a pause in the pulse at the wrist and a pause, equal to two beats, in the sounds at the apex. Pyrexia might be present. The degree (*c*) could be recognised by the very slow ventricular rate—less than 35 beats per minute. The chief symptoms of heart-block occurred when a partial block changed to a complete block. When ventricle paused for: (*a*) six seconds there was syncope; (*b*) 12 seconds, twitchings; (*c*) 18 seconds, convulsions. Treatment consisted in administering pot. iod. in full doses, both in syphilitic and other forms, while atropine diminished the number of "fits" when these were frequent. The prognosis was good if the condition was acute; if chronic the patient might have several years of useful life. *Pulsus alternans* was a condition in which there were alternately large and small beats equally spaced, but the finger often not sufficiently sensitive to detect it. Alternation was more obvious after premature contraction and the patient was of arterio-sclerotic age. The outstanding symptom was dyspnœa. The heart was enlarged, and albumin was present sooner or later. Angina only rarely occurred. The prognosis was very grave; it was extremely rare for a patient to survive two years. Treatment consisted in rest and digitalis, but intolerance was often present. Dr. Gosse said that the study of the arrhythmias was of increasing interest with increasing experience, and in no other branch of medicine was diagnosis more exact than in that of the irregular pulse. Some typical electrocardiograms, to illustrate the lecturer's points, were shown.

(*To be concluded.*)

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

An Unknown Disease Among Fishermen.

A PECULIAR epidemic has broken out among the fishermen of the Kurisches Haff, a bay in Eastern Prussia. The disease begins with symptoms of general weakness and severe pains in the muscles, which overtake the fishermen during their work, and soon a rigidity of the muscles appears which renders movement impossible. The disease develops, as a rule, in the early morning when the air is misty, but sometimes also when the fishers have come home. Anglers become more frequently ill than net fishermen, and of two fishers in a boat the man who takes up the fishing line falls ill, whilst the man at the helm is not affected. Hitherto 300 cases have been notified with 3 deaths. Only fishermen and people working in the neighbourhood of the bay caught the disease; the peasants have been immune. In some places also dogs, cats, geese, and ducks have died from it. Investigations carried out in the Hygienic Institute of Königsberg University and in the Koch Institute at Berlin have produced no result. The Health Office has accordingly sent Prof. Lentz to the scene of the epidemic for special investigation. He states that a similar epidemic has never been observed, and its cause has not yet been ascertained. It is, however, very likely that the disease is not caused by parasites, but by a poison contained in the water of the bay. It is not unlikely that the agent of the disease is a gaseous poison inhaled by the fishers. Prof. Lentz is of the opinion that the symptoms bear some resemblance to poisoning by hydrides of arsenic or phosphorus, although they less frequently lead to a fatal issue. The water of the bay is indeed spoiled by the waste water from the cellulose factories of Königsberg containing concentrated sulphides of potassium. The fishermen have drawn attention to the fact that the algæ of the bay have this year flowered for the first time in many years, and that they have afterwards shown a fermentation with a pungent odour, especially in the morning hours. The fishermen, very poor people, are badly affected by the epidemic; they are afraid of sailing to the bay lest they become ill again and customers decline to buy the fish, although nobody has become ill from eating it.

Inaccurate Death Certificates.

The Statistical Office has drawn the attention of the medical profession to the fact that in the certificates of death of elderly people very frequently exhaustion, inanition, marasmus, debility, &c., are stated as cause of death. The office has reason to believe that at least a part of those deaths is due to starvation as a sequel of financial breakdown. It has been observed that medical men have used the above rather indefinite terms in cases of death by starvation out of regard for the family of the deceased; through a special inquiry into the circumstances the true cause of death was then ascertained. Certificates of death are, according to the statements of the office, sometimes inaccurate in other cases as well. Cardiac weakness, general debility, and other diagnoses of that kind ought to be avoided as much as possible and more accurate terms used. In cases of cancer, tuberculosis, and venereal diseases, not only the disease itself, but also the organ which was the seat of the disease, ought to be mentioned in the certificate. If the death is connected with pregnancy, delivery, or abortion, this fact must be mentioned. Accurate statistical records are of great importance because they enable the government to take measures of prevention and to combat certain diseases.

Treatment of General Paralysis by Recurrens Spirillum.

It has been established that treatment of general paralysis may be carried out not only by injections of malaria germs as devised by Prof. Wagner-Jauregg (some results of which I described in my letter of

Sept. 6th), but also by injections of the spirochæte of Obermeier. Before the Medical Society of Jena Dr. Bioning gave a report of the results obtained in the clinic for mental diseases of that university. In 5 out of 30 cases where injections had been performed, a complete remission had taken place, so that the patients were able to work again with, at the most, only slight psychical defects. In four cases remission was incomplete as psychical defects remained, although the patients had become able to do easy work and behaved apparently quite normally. In 8 cases no improvement was obtained, and 13 cases died. The high death-rate was not caused by the injection, as many of the patients were in an advanced stage of the disease and died from the ordinary complications of general paralysis. In 3 cases only could the treatment be regarded as the cause of death. The after-treatment consisted in injections of neosalvarsan. Cases treated in the initial stages of the disease and those showing maniacal symptoms gave the best results.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Approaching Hygienic Congress in Paris.

THE eleventh hygienic congress, organised by the Society of Public Medicine, will be opened on Oct. 21st in the large amphitheatre of the Pasteur Institute, under the presidency of the Minister of Public Instruction and of the Minister of Labour and Hygiene. The question of instruction on hygiene will be considered in full. Dr. Bequidt will deal with the teaching of hygiene in France and Dr. Léon Bernard with the problem as it is met abroad—in the primary and secondary schools, in technical colleges, in military schools, and in the various medical schools. Dr. Humbert, who is at the head of the Section of Hygiene of the League of Red Cross Societies, will describe the rôle which the Red Cross plays in different countries in imparting hygienic instruction in primary schools. Dr. Salmon will speak on the protection of public health in England, particularly with regard to child welfare and the teaching of practical hygiene (considerations which arose through the interchange of sanitary experts with Great Britain in March and April of this year). Madame Montreuil-Strauss will tackle the delicate question of the possibility of giving hygienic sexual instruction to young girls in France. Several communications, together with a report by Dr. Diénert, will be made on the purification of waste water (chemical purification, biological purification, spraying, activated sludge, &c.). The final item on the programme of the congress will be an excursion to Rheims on Oct. 24th.

Sunday Closing of Chemists' Shops.

The Prefect of Police has recently decreed the total closing of chemists' shops in the whole district covered by the department of the Seine. A roster has been drawn up to indicate the chemists' shops which, in rotation, will remain open on Sundays to deal with emergency demands. The roster will be changed every three months. Chemists whose shops are closed on Sundays will be obliged to exhibit prominently in their windows a legible placard setting forth the names and addresses of their nearest colleagues who are carrying out the emergency services on any particular Sunday. This decree has raised much protest both from the public and from the many chemists who preferred the old system, by which there existed a personal "entente" between the apothecaries in each district, whereby an adequate Sunday service was provided through mutual agreement. The Parisian Pharmaceutical Syndicate and the Syndicate of the great French chemists denounce this new system of rotation. In their opinion rotational service will not meet the many and varied needs of the Parisian populace. The system is entirely arbitrary, and is organised on an artificial basis; consequently it cannot mould itself to requirements which in one district are totally different from those in another, or even vary from the boulevard to the street round the corner. It would seem to be a dangerous expedient to compel the public, at the beginning of the winter season, to seek out far-distant chemists on a Sunday under the pretext of fairness to all.

Doctors' Social Clubs.

Medical men who reside in Paris but are not natives of the capital are fond of grouping themselves into little social clubs, according to the district of their birth. These societies exist purely to maintain friendly relations with "compatriots," and give an excellent pretext for more or less frequent banquets. Some of these societies bear such titles as the Amicale des Médecins de Bretagne, the Société des Médecins Toulousains, l'Union Médicale Franc Courtoise, and the Nord Médical, whose members all hail from the North of France, the Pas de Calais, the Somme, the Aisne, and the Ardennes. A new society, whose possibilities have hitherto been neglected, has just been called into being, and it is that of the "Médecins Parisiens de Paris." Prof. Charles Richet is the honorary president, and at the inaugural meeting he pointed out how happy and opportune was the foundation of such a society. "Does there exist a more lonely man," he said, "than the true Parisian in his native city? On every side he sees his fellows united together by the ties of their local church bells, while he has no bond of union with those who claim Paris as their mother."

Among the doctors' clubs, where the profession alone is the binding link, may be mentioned the "Orchestre Médical," which was in existence before the war, and which has lately been reorganised. Membership is extended to all medical men, their families, and to students who perform on some musical instrument. Rehearsals are held twice a month in the headquarters of the Association Générale des Etudiants, and several excellent concerts have already been given. Medical men who cultivate the arts of sculpture, painting, and engraving have also their society, which this year held its fourth successful exhibition.

Antityphoid Vaccination in the Civil Service.

The excellent results obtained in the army by antityphoid vaccination are well known, and since the war it has been observed that the immunity conferred by the vaccine has remained effective for lengthy periods. The male population of the country who were mobilised and underwent inoculation is much less affected with typhoid to-day than are the women and children. Out of 621 cases, 145 were men, compared to 476 women and children. Several public services, in particular the Administration Général de l'Assistance Publique of Paris, have already made vaccination compulsory for certain of their employees. The public, no less than the services, ought to have recourse to this vaccination, in order still further to reduce the death-rate from typhoid fever, which has declined to 0·7 per 100,000 in 1923 from 5 per 100,000 in 1918. Mr. Louis Mourier recently introduced a Bill in the Chamber of Deputies to render antityphoid vaccination compulsory to all entrants for the civil services, both local and general. It is not easy, he said, to stimulate individual interest on the question, and therefore it behoves the law to deal with the matter as far as the public services are concerned, for it is the social duty of public servants to assist in the suppression of typhoid by themselves being vaccinated. The Bill contains the two following clauses: (1) As from the date when this Bill comes into effect, every candidate for the public service of the State, of the department, or of the Commune must prove that he has been subjected to antityphoid vaccination; (2) accepted candidates cannot be exempted from vaccination without a medical certificate setting forth the reason for such exemption.

BRITISH ORTHOPÆDIC ASSOCIATION.

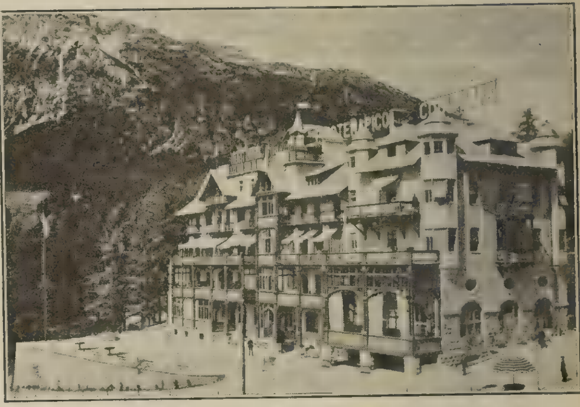
Meeting at Bologna, Italy.

Last year the British Orthopædic Association held a meeting in Holland, at the invitation of Dr. Murk Jansen at Leyden; and a joint meeting at Amsterdam in conjunction with the Dutch Orthopædic Association. The innovation thus made was so much appreciated by the members who attended that it was decided to hold another continental meeting this year. At the invitation of Prof. Victor Putti of Bologna, some 50 members and guests visited that ancient city and seat of learning on Monday, Sept. 22nd, to hold a meeting at the Rizzoli Orthopædic Institute, of which Prof. Putti is director. This institution was founded by a well-to-do and charitable citizen of Bologna, in whose memory the Via Rizzoli has been renamed, and it is housed in the splendid buildings of the old Monastery of San Michele-in-Bosco, which stand on a well-wooded hill, a short tram ride from the centre of the city. The buildings, which were erected in the sixteenth century, contain a splendid vaulted corridor of great width and height and nearly 500 feet in length, upon which some of the wards—formerly monks' cells—open. The gem of the monastery is the Aula Maggiore, now used as the library, a noble room of fine proportions decorated with beautiful frescoes. In the operating theatre Prof. Putti gave a demonstration of the reduction and plaster treatment of congenital dislocation of the hip. This deformity is extraordinarily common in northern Italy, for at this institution more than 400 cases are treated annually, while at Milan Prof. Galeazzi treats at least 500 in a year. The excessive liability of female infants to this condition is as marked in Italy as in England and other countries.

Some Members of the Party.

In the foreground, left, is Prof. Putti. Among the visitors are, reading from left to right: Miss Forester Brown, Mr. Thurstan Holland, Mr. W. Rowley Bristow (Hon. Treasurer of the Association), Mr. H. A. T. Fairbank, Prof. P. Haglund (Stockholm), Sir Robert Jones, Mr. C. Max Page, Prof. E. W. Hey Groves, Dr. Murk Jansen (Leyden), Mr. Harry Platt, Mr. Muirhead Little. Mr. R. C. Elmslie (Hon. Secretary of the Association), Mr. F. C. Pybus (in foreground), Mr. E. J. Blackett, Prof. D. P. D. Wilkie, and Prof. A. Calvé, of Berck-Plage (extreme right).

The visitors were much interested to see in the wards some quite small children, whose first plaster-of-Paris splints had been removed, exercising their own hips by means of pulleys under the supervision of nurses. This proceeding helps in the development of the acetabulum, prevents stiffness, and incidentally gives the patients some muscular exercise. Prof. Putti also exhibited a very interesting series of radiographs of congenital dislocation before and some years after reduction, in which the various degrees of development of the iliac portion of the acetabulum were well shown. After al fresco lunch in the beautiful grounds of the institute a visit was paid to the extensive workshops, in which all kinds of appliances and apparatus used in orthopædic work are made. The elaborate and ingenious table used for the treatment of fractures and dislocations was examined with much interest. Those who have seen the scamnum of Hippocrates, recently imported from Italy to the Wellcome Museum, must have reflected on the advance made on that primitive appliance, which nevertheless contained in embryo the root idea of all fracture tables. In these workshops appliances and artificial limbs are made for hospitals and practitioners in all parts of Italy. A very complete illustrated catalogue makes it easy for practitioners at a distance to select the appliances which they wish to order.



The Codivilla Heliotherapeutic Institute.

In the evening the annual dinner of the Association took place in the Hotel Baglioni, with the President, Sir Robert Jones, in the chair. More than 50 members, ladies, and guests were present.

On the second day Prof. Putti performed three typical operations—an arthroplasty of the knee by his well-known method, a tendon transfer operation for partial palsy of the foot and ankle muscles, and an open operation for congenital dislocation of the hip. Prof. Putti's skilful technique and neatness and quickness are supplemented by excellently organised team-work by his assistants. Some of his results in arthroplasty of the knee were shown by Prof. Putti at the meeting of the International Society of Surgery in London last year. The operation consists essentially of the partial resection of the joint, which should be neither too extensive nor too sparing, and the exact adjustment of the articular surfaces by means of gouges and files. The raw bony surfaces are then covered by free flaps of fascia lata, sewn into position, and the joint reconstructed by careful suture of the muscles, &c.[1] The method has been fully described in the journal *La Chirurgia degli Organi di Movimento*, but in London it was, of course, impracticable to show the actual technique on which so much of the success of the operation depends. Prof. Putti has operated on some 200 cases by his method, of which 60 were of stiff knee, and the rest of the lower jaw, the elbow, hip, fingers, and other joints.

After hearing an address on the history of the University of Bologna delivered by Prof. Putti in the beautiful old anatomical theatre of the Archiginnasio, and enjoying his hospitality at dinner, the party set out early on the next morning by train to Mestre, and thence by motor-cars through Theviso, Belluno, and the Paive Valley to Cortina d'Ampezzo in the Dolomite country, in order to inspect the Codivilla Heliotherapeutic Institute for Surgical Tuberculosis. This Institution commemorates in its name the predecessor of Putti in the directorate of the Istituto Rizzoli. Before the war it was a hotel, and has now been converted into an excellent hospital. It is situated over 4000 feet above the sea, facing due south, with high Dolomite mountains to the north and at the sides of the valley, but not so placed as to obstruct the full effect of the sun's rays. It was opened in January last with 100 beds, 50 of which are at present occupied. Patients are brought from Bologna by ordinary train and narrow-gauge railway with one change, necessary owing to the break of gauge. Here treatment as at Leysin is carried out on cases of surgical tuberculosis. In the winter bed-ridden patients are exposed to the sunshine as long as the temperature is not below +8° C. (=46° F.), while ambulant cases play about naked in the snow in temperatures as low as −10° C. (=18° below freezing point Fahrenheit). In dull weather the mercury-vapour quartz lamp is used. A careful study is being made of the local meteorology and of other conditions effecting cure. Prof. Putti pointed out as one of the problems needing solution the occurrence of cases which do well in high altitudes and badly on the sea coast, and of others of which the converse is true, although clinically no difference may be detected in the type of case.

Several interesting and memorable excursions were made by the visitors among the scenic beauties of the Dolomites.

---

[1] THE LANCET, 1923, ii., 171.

SOCIETY FOR THE STUDY OF INEBRIETY.—At a meeting to be held in the rooms of the Medical Society of London, 11, Chandos-street, London, W., on Tuesday, Oct. 14th, at 4 P.M., Prof. W. E. Dixon, F.R.S., will open a discussion on Cocaine Addiction.

STREET NOISES IN MANCHESTER.—The Manchester Watch Committee have decided to issue a warning to motorcyclists to the effect that the nuisances created by the absence of or the failure to use silencers on their machines, and by opening the throttles to accelerate speed, must cease at once. In future all offenders within the Manchester boundaries are to be prosecuted. A large number of complaints have been received by the police, especially at week-ends.

MATERNAL MORTALITY.

CONFERENCE AT THE ROYAL SOCIETY OF ARTS.

A CONFERENCE organised by the Post-Certificate School, on the Means of Reducing the Maternal Mortality-rate by the Coöperation of all the Health Services, took place at the Royal Society of Arts on Oct. 6th. The chair was occupied by Dr. J. S. Fairbairn, who opened the proceedings by reading two letters, one from Mr. Wheatley, Minister of Health, the other from Sir Francis Champneys, who emphasised the importance of tracing all persons who had to do with a patient, especially as to who delivered her, and the need for cordial coöperation between all who have to deal with the patient.

Right Method in Antenatal Care.

Mr. Aleck Bourne, who opened this subject, said that need for antenatal examination and interview of every pregnant woman was agreed upon by everybody with any knowledge of modern obstetrics. When it was realised that the vast majority of all the dangers and disasters of midwifery were preventable by examination and correction during pregnancy, no further justification was required. Women themselves seldom offer any objection to being examined, in fact, they are beginning to expect it, and express surprise when it is neglected. So important is the matter of detection and elimination of possible difficulties in confinement that it is justifiable to refuse attendance or admission to a hospital of a woman who will not submit to antenatal examination. In addition to the routine examination of private patients it is essential to organise facilities on a wide scale. These may take the form of :—

(*a*) Centres or clinics established ad hoc, and run by paid part- or full-time officers.

(*b*) Establishment of an antenatal out-patients' department in all big voluntary hospitals in connexion with their in-patients' maternity wards. There would be three classes of patient : (1) those booked for admission to the wards for their forthcoming confinement ; (2) those to be attended in their own homes by the students or pupil midwives of the hospital ; (3) those referred by practitioners for an opinion in cases of suspected difficulty. This third type of patient is the one to be encouraged. It is important to try to establish the hospital clinics as consultative centres which shall gain the confidence of local practitioners and midwives. They should feel that they will have an opinion and necessary guidance from a specialist in the subject. Great care should be taken to foster the use of the hospital clinics by doctors and practising midwives by such simple courtesies as sending the patient back with an explanatory letter.

(*c*) The smaller country hospitals should similarly develop their own local antenatal clinics, meeting at a definite day and time known to all the local doctors and midwives. It is essential that these cottage hospitals clinics should be staffed by a doctor who has taken the trouble to learn the system by visits paid to a lying-in hospital and who has earned the confidence of his local colleagues by his special knowledge of obstetrics. Similarly, the urban antenatal centres should be staffed by medical officers who have had some real instruction and experience in antenatal work, and appointing bodies should demand evidence of such experience before selecting the candidate. A thorough-going antenatal organisation would ensure the examination of every pregnant woman and detection of a vast proportion of abnormalities which, while potent causes of disaster in labour, would be rendered harmless by suitable treatment or correction.

Midwives, Trained and Untrained.

Dr. J. W. Wayte underlined the importance of the trained midwife as the chief lieutenant of the general practitioner, adding that the presence of under-trained and inexperienced midwives is a source of weakness to the otherwise well-laid foundations of the services of the practitioner and the local supervising authorities. Dr. Wayte pointed out that the practitioner only books a third of the number of confinements he formerly attended in the course of the year, and in consequence the work has passed largely out of the hands of a skilled practitioner into those of the relatively less skilled practitioner—the midwife. Moreover, a great diminution of individual experience of the general practitioner is caused by two-thirds of his cases now being divided amongst a number of midwives. After paying a tribute to the excellence of the trained midwife, Dr. Wayte said that though there are times when the doctor is tempted to interfere too soon and hurry a delivery, since he has the power and ability to apply forceps, and that this may be an error of judgment, a misapplication of skill, and certainly a predisposing cause of sepsis, possibly death, as a matter of fact, nowadays the opposite state of affairs obtains and death is more often caused by interference being left too late. Perhaps the doctor is at fault, perhaps the midwife, but only too frequently it is because the two do not work together. Dr. Wayte's opinion of the ideal future method of conducting a birth is always to have both doctor and midwife available, not necessarily both present, but both available with mutual confidence. He admitted that the objection to this ideal was the general lack of money and the temptation to dispense with the services of a medical man as more midwives were available. He also predicted that in the near future, when the midwife has essentially longer training of a full year, she may ask rather larger fees. The solution offered by Dr. Wayte to the above difficulties was that local authorities should be asked to provide more beds in institutions, staffed by skilled midwives with a visiting medical staff and available for those very vital emergencies of general practice which need experience and skill. After stating that yeoman service had already been done in this direction and many maternal and infant deaths averted, Dr. Wayte concluded by saying that he would have liked to have compared and contrasted mortality in primiparæ and multiparæ—the different causes and consequences in the two states, a question which the practitioner and midwife should be technically qualified to discuss.

Rôle of the Supervising Authority.

Dr. E. F. Palgrave, speaking his personal views, outlined the rôle of the supervising authority in relation to the doctor, the midwife, the handy woman, the patient, and corporate bodies. In relation to the doctor, he said he would like to see the authority given power to pay special fees in special cases when the doctor's attendance would be given free to the patient. He emphasised the importance of friendliness and close coöperation with the midwife, and said that inspection was no good without instruction. More formal instruction was necessary and should be at the service of the midwife to keep her up to date. The L.C.C. this autumn, in addition to usual courses of lectures to midwives, are giving special courses of antenatal demonstrations in six lectures by the best teachers. In regard to the handy woman, Dr. Palgrave said that if she must be recognised as a necessity she should be under some kind of supervision and both registered and inspected, as there was no hope for improvement till she was under control. In regard to the corporate bodies (Ministry of Health, C.M.B., General Medical Council, sanitary authorities, hospitals), Dr. Palgrave suggested the formation of a round-table conference between the local authorities and the C.M.B., as he believed that by means of open discussion many deaths could be averted.

Provision by the Poor-law.

Dr. E. W. G. Masterman (St. Giles's Hospital) gave an interesting account of the provision for expectant and lying-in mothers under the Poor-law, pointing out that housing difficulties since the war have caused respectable married women to have their confinements in Poor-law institutions. Among recent developments mentioned were the admission of patients without the intervention of relieving officers, admission as "municipal council cases" of (*a*) those with deficient housing accommodation, (*b*) those needing special surgical treatment. A separate maternity home with separate entrance has been carved out of the workhouse. In Bradford 500 maternity cases are treated annually. In London area the North Middlesex Hospital caters for Tottenham, Enfield, Edmonton, and Hornsey. There are similar arrangements at Willesden and a scheme nearly ready at Hampstead. Dr. Masterman also spoke of the instruction now given to candidates for the C.M.B. among trained nurses, no less than 200 qualified nurses being yearly prepared in infirmaries in and around London. In St. Giles's Hospital eight candidates will be trained yearly, and at several Poor-law hospitals post-graduate lectures are organised by the London County Council.

The View of the General Public.

Mrs. Bruce Richmond, speaking on behalf of the public, said that the fact that more women died in childbirth in England than in Italy or other countries touched the Briton on a tender spot. Discussing different points in Dame Campbell's report, Mrs. Richmond laid stress on the different standard of aseptic care and personal clearliness shown by attendants at a confinement, and thought that the doctor should be made responsible for any infringement of rules as much as the midwife. In considering antenatal care, she thought that blame for the trouble following this omission should be attached to the doctor or midwife, and that there should be a standard of efficiency at antenatal clinics to obviate variety in the value of advice given. The difficulty of obtaining antenatal care in scattered districts could only be solved by midwives attending normal cases with adequate medical advice available when needed. Mrs. Richmond strongly deprecated the employment of so dangerous a person as the "handy. woman" and advocated her elimination, as well as that of the unqualified man practising midwifery, by an alteration in the Midwives Act. In order to attract better educated women to a profession, admittedly both strenuous and badly paid, Mrs. Richmond advised their being treated more as other professional women are treated, and given the honoured place they deserve. Public health authorities should show themselves more sympathetic towards midwives and never require them to disinfect at common cleansing stations or institute other rules than those of the Central Midwives Board, as no intelligent well-educated woman can keep herself up to date if her local authority dictates her working method. Mrs. Richmond also advised a reorganisation of health services to prevent overlapping. The midwife will, with additional training, be qualified to do her own health visiting with greater possibilities of influence gained by uniformity of advice. Where Dame Campbell urged available maternity beds for the poorest patients, Mrs. Richmond suggested a uniform method of inspection and standard of efficiency for all homes, municipal or private, and pointed to existing schemes giving relief, in the home or not, which neither limit the patient's freedom to choose their attendant nor subsidise particular midwives or homes to the detriment of others.

Education as the Solution.

Miss Liddiard (Mothercraft Training School) proposed education as the remedy for maternal mortality; education of the general public, men as well as women, through the medium of women's institutes, mothers' unions, men's clubs, and so forth. This education, she said, should be given to women of all classes, and the expectant mother should be taught the immense importance of general health on pregnancy, labour, ability to nurse her infant and give it the best start in life, as well as taught to demand antenatal supervision, examination, and urine-testing, &c. After this comes the education of the mother as to the right feeding and care of the child in order to prevent rickets, and the early education of the school-girl in the ideals of motherhood.

The Chairman, after summing up the keynote of the conference as coöperation, invited discussion from the audience.

Discussion.

Mrs. F. Stobart suggested that women's institutes should be asked to give regular courses of lectures all over the country wherever there was a demand for them.

Miss Olive Haydon (York Road Hospital) said that each case should be studied to decide if it is suitable to be handled by a midwife alone, that 90 per cent. of labour might be normal, a fact not widely enough known, and that if the midwife could not distinguish between normal and abnormal cases she should not practise. If the midwife were able to call in not only the general practitioner but the expert many lives would be saved.

Miss R. Paget (Queen Victoria's Jubilee Institute) said she would like to make two practical if controversial suggestions: (1) That a post-mortem examination by Government officials should be held on every woman who dies in childbirth, whether rich or poor. (2) That it should be a penal offence for any person not a doctor nor a midwife to examine a woman internally. Miss Paget agreed with Sir Francis Champneys as to the importance of stating who delivered the patient on the notification of birth certificate, and she added that the midwife needs good consultants and she should be inspected by whole-time, thoroughly well equipped inspectors, and should be qualified professionally, mentally, and personally. Such women should be encouraged to practise instead of wasting their training by taking up other better paid jobs. Miss Paget ended by advising that at every wedding the husband should be presented with a manual enjoining consideration for the health of wife and future children, a course also advocated by the next speaker, Mrs. Milligan, member of the Surrey County Council.

Miss Wilmeshurst said that lives were sometimes imperilled by the lack of coöperation between the inexperienced student and his assistants, and that the student should be trained to look on the midwife and trained nurse as his co-workers instead of regarding them as handy women.

Dr. Harold Scurfield noted that all speakers had insisted on antenatal work as crux of any life-saving programme, and pointed out that outside the London area practically no antenatal work worth the name was going on in the country districts. The work of midwifery in many districts is passing from the doctor to the midwife, who needs expert advice. He had come across lately many instances of unemployed yet fully trained women doctors, and he suggested that these surplus doctors would constitute a good service to come to the aid of the midwife if trained as obstetric specialists. In Liverpool 90 per cent. of the cases are delivered by midwives and only about 20 per cent. of them send for the doctor. There were not enough antenatal specialists throughout the country.

Dr. Elizabeth Macrory (Inspector of Midwives) said that prenatal examination should not only be made by a skilled person, but a doctor should be present, or if not the result should be communicated to him. She also said that the sanitary authorities might help to lessen mortality in cases where removal to hospital was not possible by the loan, to be paid for if possible, of a provision of sterilised towels, &c., and that some proof of obstetric experience beyond that of student qualification should be required of students sent out to take confinement cases; they should be accompanied by someone skilled in at least normal obstetrics and a consultant should be available.

Miss Elsie Hall pointed out that if skilled inspection throughout the country could be ensured it would improve the education of the midwife.

Miss Sparks (Middlesex Hospital) thought that the midwife should also be a trained nurse.

The Chairman, in summing up, said that all deaths in childbirth should be investigated by the local authority, and that examination should take place not when the patient has succumbed but at the beginning of puerperal fever.

THE LONDON MEDICAL EXHIBITION.

A REVIEW OF THE EXHIBITS.

AT the Medical Exhibition organised by the management of the Seventeenth International Congress of Medicine, 1913, and the Fifth Clinical Congress of Surgeons, 1914, in the Central Hall, Westminster, London, S.W., which opened on Oct. 6th and closes to-day (Friday), a most informative collection of drugs and appliances used in the art of medicine and surgery, organo-therapeutic, bacteriological and pharmaceutical remedies, electro-therapeutic apparatus, and many ancillary agencies, such as dietetics, and hospital and invalid furniture, were displayed. The medical man is essentially a student, but in these days progress is so rapid that even the attendance at post-graduate courses hardly suffices to keep the practitioner abreast of present-day treatment. An exhibition of this kind affords an opportunity to the busy practitioner to see the products and inventions which follow so closely on advances in treatment or technique, and to appreciate the labours of the various firms who, in response to the scientific requirements necessitated by research, administer to the needs of medicine and surgery. That the exhibition really fills a need is shown by the large number of medical men who visited it between the hours of noon and 6.30 P.M. each day, and by the keen interest which they took in the exhibits. In addition, the exhibition afforded an opportunity for friendly discussion and social intercourse, for which arrangements were made by the organisers, while the presence of many foreign and overseas visitors, some 300 of the latter having applied for tickets, showed the wide appeal of this display of scientific medicine and surgery.

Many of the exhibits have already received attention in our columns, and for the convenience of readers we append at the end of this article a reference to our pages where more recent notices of interesting or noteworthy products or inventions have appeared.

The overlapping by many of the firms of medical and surgical exhibits, and the many adjuvants to both branches, make it impossible in describing the exhibition to adopt any scientific classification, but for convenience we take as main headings Drugs and Foods, Instruments and Appliances, Milk and Its Preparations, Spas and Waters, and Medical Books.

Drugs and Foods.

One of the first exhibits that caught the eye of the visitor was that of ALLEN AND HANBURYS, LTD. (37, Lombard-street, E.C., 7, Vere-street, W., and 48, Wigmore-street, W.), with its sections of pharmaceutical products, organo-therapeutic products, and surgical instruments. A prominent display is made of "Osmo" Kaolin,[1] a specially purified kaolin prepared by electro-osmosis, which has proved useful in the treatment of toxæmias of intestinal origin. Liquid extract of ergot, containing a standardised proportion of physiologically active constituents of ergot, was another preparation which attracted many visitors, as did also Saccharomycin, an isothermal, isotonic, and living yeast, which is supplied in fluid form in sterilised ampoules of 1 c.cm. for oral administration. Organic antimony compounds, which have been used with success in the treatment of tropical disorders, were also prominently exhibited, as well as this firm's foods for infants, Bynol and Bynotone,[2] Diabetic Flour,[3] and its preparations.—The varied products of the firm of BURROUGHS, WELLCOME AND CO. (Snow Hill Buildings, E.C.) were prominently displayed and were the centre of constant inquiries. A prominent feature of the stand was "Tabloid" Hypodermic Insulin Hydrochloride (Sterile), which is convenient to administer, readily portable, and may be dissolved within the syringe. The "Soloid" Urine-Sugar Test Case, which was also shown, is designed further to facilitate the examination of diabetic urine. This small portable case contains all the essentials for the quantitative determination of sugar. "Soloid" Benedict Test supplies a simple method of performing this delicate test. Among gland products was Parathyroid[4] and the Wellcome Sera and Vaccines, produced at the Wellcome

Physiological Research Laboratories, were also shown, as well as "Ethidol," a colourless, non-irritating liquid, containing 20 per cent. of iodine, for intraglandular injections and inunction. The external use of "Ethidol" in conjunction with the internal use of Iodicin enables the iodides to be intensively exhibited. Chemicals and Soloid products were exhibited in large variety, and interest was shown in the Tabloid medical equipments and first-aid outfits with which American and British airmen were equipped in the recent round the world flights.—BOOTS PURE DRUG COMPANY, LTD. (Nottingham), showed a comprehensive display of synthetic and medicinal chemicals, compressed drugs and tablets suitable for rapid solution of drugs for external application, &c., pharmaceutical preparations, and so forth. All these are manufactured under rigid analytical control conditions, thus ensuring definite therapeutic action. Among arsenical preparations was Stabilarsan.[5] Dressings and sundries formed another section of this characteristic exhibit, which enabled inquirers to select for immediate or future use almost everything that a medical practitioner may require in general practice. Insulin was a special feature of this exhibit and practical demonstrations of MacLean's apparatus for blood-sugar estimations were given.—A particularly interesting exhibit was that of the ANGLO-FRENCH DRUG CO., LTD (238A, Gray's Inn-road, W.C.), who had a wide display of pharmaceutical preparations, including Dimol, an intestinal disinfectant in the ordinary form of pulverettes and syrup, as well as in the new forms of dentifrice, ointment, and pastilles. Cardibaine,[6] known in France as Ouabaine, a chemically pure crystallised strophanthin, and Digibaine,[6] an association of strophanthin and digitalin, were also shown, and a large number of intravenous solutions for various purposes. Pharmasols, pharmaceutical colloids, were a special feature of this exhibit, and particular attention was called to Oragol, an electrically prepared suspension of colloidal silver and gold for infectious conditions in nose, throat, and eye affections. The preparation is put up in an attractive case with a dropper and nasal douche. Néocaine, with the Gaston Labat syringes and needles, were also shown.—Among the fine display of colloids by the CROOKES LABORATORIES (British Colloids, Ltd., 22, Chenies-street, W.C.) was Ichthyol, prepared from the distillation of fossilised marine deposits found in the Norfolk oilfields. This, it was particularly pointed out, is a natural product and not a synthetic preparation. Collosol Iodo-Cataplasma, for use in the place of ordinary poultices, also received marked attention.—A noteworthy exhibit was that of the BRITISH ORGANOTHERAPY CO., LTD (22, Golden-square, Regent's-street, W.). Here was displayed a selection of scientific organo-therapeutical products, both for oral and hypodermic administration—monoglandular and pluriglandular products, which, it was pointed out, are made from fresh materials (within a few minutes of the death of the animal), and every animal used has to pass a stringent examination by a veterinary surgeon before the required glands are dissected. Among the products exhibited were Lymphoid Compound, for functional nervous disorders; Lymph Serum, for degenerative, mental, and nervous conditions; Evatmine, for asthma; and Pancreatokinase, for diabetes mellitus and glycosuria.—The principal exhibits of the ANGLO-AMERICAN OIL CO., LTD. (Albert-street, Camden Town, N.W.), were Nujol and Mistol, the first being a paraffin product of exceptional purity used as an intestinal lubricant, and the second an oily solution for use in an atomiser by means of which the soothing and antiseptic properties of camphor, menthol, and eucalyptol, are brought into intimate contact with the mucosa of the nose and throat.—At the stand of G. W. CARNRICK CO.'s Standardised Gland Products (London Agents, the A.D.S. Co., 40–42, Lexington-street, W.) preparations were exhibited in variety and particularly for use in menstrual and menopausal disorders and in neurasthenia (Hormotone); diabetes (Trypsogen); gastro-intestinal disorders (Secretogen); and as an aid to metabolism in tuberculosis, malnutrition, &c. (Kinazyme).—Much interest was shown in the stall of ENDOCRINES, LTD. (72, Wigmore-street, W.), where there was a large collection of pluriglandular preparations of the Harrower Laboratory known as "Polycrines." This laboratory prepares 33 various combinations of the endocrine glands in tablet form for oral administration and four combinations of glands in the form of solution for hypodermic injection. The latest addition to the list is a nucleoprotein solution of parathyroid and spleen (Sol. Para-Spleen Co.) put up in ampoules. This is a special product of the Harrower Laboratory. A vest-pocket "Manual of Pluriglandular Therapy," containing 290 pages, is distributed by the firm for the use of medical men.—The original preparations of C. J. HEWLETT AND SONS (35–42, Charlotte-street, and 83–85, Curtain-road, E.C.) drew attention by reason of their external attractiveness no less than by their indicated use. These included antiseptic cream for eczema, abrasions, &c.; Mist. Pepsinæ Co. c. Bismutho, as a remedy in dyspepsia, gastrodynia, pyrosis, gastritis, and sickness; and Evapogens, a series of medicated skin lotions, containing spirit, that rapidly evaporate on the skin. A special feature of the exhibit was Dr. Crofton's Human Tubercle Bacillus Solution for the immunisation treatment of tuberculosis.—Among the large selection of preparations for use in the treatment of syphilis exhibited by MAY AND BAKER, LTD. (Battersea, S.W.), was Novarsenobillon ("91"), Arsenobillon ("606"), Arseno-argenticum, and Eparseno ("192") amino-arseno-phenol, the base of "606" combined with glucose. This is used in syphilis, yaws, recurrent fever, and has had marked success in leprosy. Stovarsol, hydroxyacetylaminophenylarsenate, is a new preparation for use in amœbic dysentery. Attention was also called to Rubyl—bismuth and quinine iodide—which in syphilis appears to be the best tolerated of the insoluble salts of bismuth.—At the stall of OPPENHEIMER, SON AND CO., LTD. (179, Queen Victoria-street, E.C.), Roboleine, the "A," "B," "C" vitamin diet, was exhibited; organic preparations in their well-known palatinoids, and argentum, cuprum, ferrum, hydrargyrum, iodum, manganese palladium, selenium, stibium, and sulphur "oscols." The palatinoid administration of hormone products was also demonstrated.—In connexion with vitamin preparations VITMAR, LTD. (Standen-road, Southfields, S.W.), showed their product, which is an intimate emulsion of ox fat, raw egg yolk, wheat germ extract, and fresh fruit juice, and has the high food value of 400 calories per 100 grammes. Its use is indicated in the treatment of all forms of malnutrition, rickets, neurasthenia, gastro-intestinal disorders, and all conditions in which a bland, readily absorbed nutrient is necessary.—A new antiseptic and germicide, Dibromin ($C_4Br_2N_2H_2O_3$), was shown by PARKE, DAVIS AND CO. (50, Beak-street, Regent-street, W.). This is a white crystalline powder slightly soluble in water, but more so in glycerine or alcohol, and by the Rideal-Walker test has been shown to be 105 times as powerful as pure carbolic acid. It is claimed to be practically non-toxic and non-irritating when used in dilute aqueous solution of 1 in 10,000 to 1 to 1000. It also does not coagulate albumin. Gland products, pharmaceutical preparations, and anti-catarrh vaccine and mixed vaccine for colds were other exhibits which excited much interest.—Scillaren,[7] cardio-tonic glucoside of squill allowing of the exact medication required in modern therapy, and a valuable adjustment to digitalis, was exhibited by the SANDOZ CHEMICAL CO., LTD. (Canal-road, Bradford), as well as Femergin (Ergotamine "Stoll"), Ipecopan, an expectorant and sedative which contains the pure alkaloids of ipecacuanha and opium, and Felamine, for treatment of affections of the biliary system. Attention was drawn to Matinol, a dietetic and digestive biscuit which regulates the intestinal functions and provides an entirely new medium for the administration of paraffin.—The preparations of SAVORY AND MOORE, LTD. (143, New Bond-street), were prominently exhibited, and special interest was shown in their foods for infants and adults. The easily digestible peptonised cocoa and milk and peptonised milk attracted many inquirers, as did also the acid glycerin of pepsin (Bullock) which has a sweet taste and agreeable flavour and may be combined with most medicinal substances with which acids are compatible. A dainty preparation of this firm is Aphrodont tooth paste.—Many inquiries were made at the stall of W. MARTINDALE (10, New Cavendish-street, W.) whose preparations made a striking appeal. Among them were two chemical substances new to medicine—namely, Aspriodine—which combines the properties of aspirin and iodides, and Sedasprin, a definite compound of bromine and aspirin. Mercurochrome,[8] an antiseptic, also produced many inquiries. Attention was drawn to the eighteenth edition of the "Extra Pharmacopœia" of this firm, which is published this week.—The display of CHARLES ZIMMERMANN AND CO. (9 and 10, St. Mary-at-Hill, E.C.) included Idozan, described as a colloidal iron concentrate for use as an oxy-hæmoglobin excitant in the treatment of anæmia, and Kathiolan "one application" treatment for scabies. Attention was particularly drawn to Asthmolysin (adrenalin-pituitary compound), a sterile and effective anti-spasmodic, for hypodermic use in the treatment of acute attacks of bronchial asthma, and to Incitamin, a comparatively new remedy for the treatment of slowly healing sores.—Interesting preparations to be seen at the exhibit of BENGUE AND CO. (52, Charlotte-street, W.) were: Dr. Bengue's Balsam, menthol, methyl salicylate, lanoline, analgesic, antiseptic; Ethyl Chloride, for local and general anæsthesia; Pulmo Bailly, for diseases of the respiratory organs, asthma, bronchitis, catarrh, and tuberculosis; and Forxol, a preparation of nucleogenic vitamins for neurasthenia and disease of nervous origin.—The Izal disinfectant specialties were shown by NEWTON, CHAMBERS AND CO., LTD. (331, Gray's Inn-road, W.C.). Izal disinfectant in the form of medical and ordinary fluids, perles, ointment, lozenges, cream, household, and toilet and medical soaps, and the "Zal" Disinfector, which is an improved form of bronchitis kettle which can be used over a gas ring, spirit lamp, &c., under circumstances where it is not practicable to fit up a steam installation. Two useful preparations of this firm elegantly put up in collapsible tubes were Izal Toilet Lano-Cream and an antiseptic shaving foam.—Among the preparations displayed by GENOTOSAN LTD. (Loughborough, Leicestershire) were the tonic food Sanatogen, a germ-killing snuff, Nasmint, Formamint, and Genasprin. Detoxicated vaccines were also shown in variety.—JEYES' SANITARY COMPOUNDS CO., LTD. (64, Cannon-street, E.C.), exhibited a large number of preparations of Cyllin which has a high bactericidal power with but slight toxicity. Among them were inhalant capsules for use in stomachic and intestinal antisepsis, syrups for infantile diarrhœa, pastilles, dusting powder, ointments, and so forth. Jeyes' Lysol (Jeysol) and Jeyes' Cyllin Veterinary 3 m. capsules for dogs were also displayed.—The stall of the HOFFMANN-LA-ROCHE CHEMICAL WORKS, LTD. (7 and 8, Idol-lane, E.C.) had a very fine display of drugs including among others "Digalen"; "Iodostarin"; Oleo-Bi[9] and Tartro-Bi; "Omnopon," total opium; "Spasmalgin"; "Thiocol"; and other well-known "Roche" products. Much interest was shown in this firm's "Allonal,"[10] or allyl-isopropyl-barbituric acid combined with phenyl-dimethyl-amino-pyrazolon, which is non-narcotic, and the claim is made that it is non-habit-forming. It contains no opium derivatives and can be used in the place of morphia where indicated.—VIROL, LTD. (Hanger-lane, Ealing, W.), in addition to their well-known specialties of Virol and Virolax, displayed Virol and Milk in powder form which, mixed with hot water, makes a useful tonic food.—OXO, LTD. (Thames House, Queen-street, E.C.), who showed Oxo in various forms, Lemco and Lab-Lemco, made a special feature of "Oxoid" Gland extracts, in connexion with which two interesting pamphlets are issued; the thyroid gland and the pituitary gland, both containing general observations on glandular therapy.—The merits of products of BOVRIL LTD. (148–166, Old-street, E.C.) are too well-known to need more than passing mention.—An attractive display of California Syrup of Figs was made by FASSETT AND JOHNSON, LTD. (86, Clerkenwell-road, E.C.).—The MALTINE MANUFACTURING CO., LTD. (9, Holborn Viaduct, E.C.), showed their malt preparation which contain the nutritive element of wheat and oats, in addition to those of barley.—J. C. ENO, LTD. (Pomeroy-street, S.E.), demonstrated the properties of their well-known fruit salt, and presented to their many inquirers a copy of "The Practitioners' Pocket Book," a useful little book containing matters of much interest to medical men.—Thermogene Curative Wadding, THERMOGENE CO., LTD. (Hayward's Heath, Sussex). This is a prepared cotton-wool with analgesic and counter-irritant properties, which has been found of use for some considerable time.—DENVER CHEMICAL MANUFACTURING CO. (London, E. 3) made a display of the now well-known Antiphlogistine, an hygroscopic and antiseptic poultice the use of which was illustrated in a series of attractive pamphlets.—Angier's well-known emulsion (petroleum with hypophosphites) was shown by the ANGIER CHEMICAL CO., LTD. (86, Clerkenwell-road, E.C.).—In addition to Pineoleum Brand Inhalant,[11] PINEOLEUM CO., INC. (American Drug Supply Ltd., 40–42, Lexington-street, W.) showed a new form of the preparation which consists of a paste in a collapsible tube. This is a convenient way of administering Pineoleum to the mucous membrane of the nose.—Prominent on the stall of PEPSODENT CO. (42, Southwark Bridge-road, S.E.) was the Decoater Tooth-brush designed for use with the tooth paste "Pepsodent." These brushes are of such a shape that the bristles penetrate to all parts of the oral cavity; they are contained in a pocket case.—KOLYNOS INCORPORATED (Chenies-street, W.C.) showed their dental cream, an antiseptic which does not interfere with the normal secretions of the mouth and makes a most efficient cleansing agent for the teeth.—KEEN, ROBINSON AND CO., LTD. (incorporated with J. and J. Colman, Ltd., London and Norwich), in addition to their well-known mustard, showed an ointment having all the therapeutic virtues of the mustard plaster, and Almata,[12] a complete food for infants, invalids, and nursing mothers. Robinson's Patent Groats and Patent Barley were also exhibited.

FACT AND THEORY IN RADIO-THERAPY.

To the Editor of THE LANCET.

SIR,—In your issue of Sept. 27th Dr. F. Hernaman-Johnson discusses some of the principles in the radiotherapeutics of cancer. In this article there are one or two passages in which the author departs from his usual lucidity, and which seem to me to afford the occasion for comment.

In the first instance, the author appears to confuse facts and theory. On p. 635 he says: "I made a statement in 1916, I think, to the effect that ultra-violet rays could not benefit exophthalmic goitre 'because they had practically no penetration'; and one sees similar statements to-day." He then refers to the fact that deep-seated lesions may be benefited by this form of therapy, cries an honest "peccavi," and then says "we should beware of denying clinical facts because of physical theories." I do not think we should blame theory here; judgment upon the physical facts has been wrong, but even the facts were right. (I join in the peccavi!)

Secondly, the author on p. 638 seems to me to invoke a theory against the facts. He is discussing the well-known clinical fact that growths become apparently resistant to repeated applications of X rays. Obviously this may be due either to the malignant cells or to the tissues of the host, an alternative not easily decided upon in the human subject. He then refers to the fact that when animal tumours are removed from the body and given repeated doses of X rays, the same phenomenon appears. The experimenter responsible for this finding has concluded that whatever the body of the host may do, the cells of the tumour thus repeatedly irradiated acquire an increased resistance to the rays. Dr. Hernaman-Johnson thinks it is perhaps simpler to assume that certain cells by reason of variation, or even of mutation, have inherently a higher resisting power; that these alone survive and their descendants inherit the favourable character. To my mind it is not a simpler assumption, and it is contradicted by the facts which form the working basis of lethal dose determinations.

Finally, a word upon the first of Dr. Hernaman-Johnson's conclusions. He says: "The wave-length most suitable for any given type of growth can be found only by clinical observation." This is an amazing statement, for if there is a laboratory investigation likely to throw some light on therapeutic probabilities I do not think that a better example could be found than this study of the animal response to measured doses of radiation of different wave-lengths.

Surely, if data of this sort were found, the experimenter would probably get from radiologists the consideration that laboratory investigations bearing on other aspects of medicine receive.

I am, Sir, yours faithfully,
Middlesex Hospital, W., Oct. 4th, 1924. SIDNEY RUSS.

DENTAL DRESSERS.

To the Editor of THE LANCET.

SIR,—Mr. A. T. Pitts in his letter on the above subject in your issue of Oct. 4th does not refer to the fact that a Departmental Commission, which sat and took evidence on how to solve the problem of dental disease as well as how to look after the interests of the dental profession, reported that local authorities could not afford to employ dentists to do the minor dental work, and that trained dental nurses might be trusted to do this work under proper supervision. A Bill was introduced to give effect to the recommendations of the Departmental Committee, and a clause in the Dentists Act enables the services of trained dental nurses to be utilised, on conditions to be approved by the Minister of Health. But the conditions now laid down by the Minister will now stop the work they have been doing in Derbyshire for the last five or six years. Mr. Norman Bennett, who gave evidence on behalf of the British Dental Association against trained dental nurses being employed on any minor operative work, was called in by the Board of Education to advise them, and two of the conditions laid down in Circular 1279 are recommendations contained in Mr. Bennett's report to the Board of Education. It is as if the town clerk of Ephesus had invited Demetrius to draft a circular giving the conditions under which Christianity could be preached without detriment to the craftsmen he represented. It would be humorous if it were not tragic.

Two important questions arise from Mr. Pitts's letter: (1) *Are these trained dental nurses efficient?* Mr. Pitts has given a verdict without any examination of their work. The work of our trained dressers has been tested by more than half a dozen different dentists, and not one has been able to say that the work is not of the highest professional standard. I will withdraw from any advocacy of dental nurses if it can be shown that the scheme is in any way injurious to the children. (2) *Is the scheme in the interest of the dental profession?* Undoubtedly it is, for if sanctioned, every authority in the country would be only too willing to provide a public dental service, and there would at once be a great demand for dentists. At the present time we are doing nothing for our antenatal mothers, whose teeth are crying for attention. This is work which should be done by dentists alone. We are doing nothing for children below school age; this is suitable work for a dental nurse working under the supervision of a dentist. Practically nothing is being done in this country for the teeth of patients suffering from tuberculosis, and above all, the Royal Commission now sitting is sure to recommend that dental treatment shall be one of the benefits to be given under the Insurance Act. This work is all work which must be done by dentists, and those who are working with me for the recognition of trained dental nurses to do "minor dental work" under the supervision of a dentist, as recommended by the Departmental Committee, will loyally support the dental profession in safeguarding their interests.

When Circular 1279 was drawn up none of the authorities who were employing trained dental nurses were consulted, either by the Board of Education or by the Dental Board. Speaking for myself, I should be perfectly satisfied if every dentist was limited to *one* dental nurse working with him, provided the work of inspection in the schools with probe and mirror were entrusted to another.

I can assure your dental readers that no member of their own profession has their real interests at heart more than myself, and unless a compromise can be effected on this question I have no doubt that a scheme on the lines of the New Zealand scheme will find its place on the Statute Book before many years.

I am, Sir, yours faithfully,
Sidney Barwise.
Medical Inspection Department, Derby, Oct. 6th, 1924.

THE LATE MR. W. H. A. JACOBSON.

To the Editor of The Lancet.

Sir,—I did not serve directly under Jacobson at Guy's, but the out-patients offered opportunities for appreciation. No one who observed him could doubt he "postulated a continuity," that he was an aristocrat and no self-made man, even if in his lectures he had never spoken of "my father the Bishop"—one of the subjects of Dean Burgon's "Lives of Twelve Good Men." Jacobson could be exacting and seemingly haughty, yet I hazard he was essentially humble, and "without humility, no veracity." A man walking up to him between rows of students, with hat on, would meet with resenting disapproval, but many a forlorn woman called forth Jacobson's practical sympathy. And now, in the faded days, I think if there was one characteristic more than another it was his glow.—I am, Sir, yours faithfully,

Dean-rd., Willesden Green., N.W. Richard Gillbard.

THE HEALTHY HEART.

To the Editor of The Lancet.

Sir,—The case of an ex-Service man who consulted me recently has some bearing on the "healthy heart." Eight medical boards of the Ministry of Pensions diagnosed his case as valvular disease of the heart, the last board making a final award equivalent to a disability of 16 per cent. for two and a half years, and then of 0·25 per cent. for the rest of his life. That, of course, must mean that the medical board were of opinion that after two and a half years the man's heart would be practically a "healthy heart"! At present there is well-marked mitral regurgitation, enlarged heart, and the "effort syndrome" which denotes impaired musculature. Can any of your readers tell me under what treatment such a heart can be restored to normal within two and a half years, or at all? The Ministry of Pensions, I may add, has refused to allow an appeal on the ground of the application not being made within the year.

I am, Sir, yours faithfully,
D. F. Shearer, F.R.C.S.
Kidlington, Oxon, Oct. 6th, 1924.

THE SLEEPLESSNESS OF ENCEPHALITIS.

To the Editor of The Lancet.

Sir,—Since the early part of the year there have been about 50 cases of encephalitis lethargica under observation at Southmead Hospital. We have experienced the usual difficulty in dealing with "the sleeplessness by night, and the sleepiness by day" in ten cases. On carefully questioning them, I found that terrifying dreams had particularly affected this class; coming on directly they went off to sleep in a darkened room; keeping them awake practically all night, until the morning light, and hence their tired condition of the next day. I arranged for a bright light to be kept burning in their rooms (night-lights are not bright enough) and tried several shades of different colours; blue is the most soothing to them. Successful results have been obtained; they have soon gone off to sleep again. By keeping them well employed during the day with outdoor exercises they are rendered so tired that they soon sleep all night, and make a rapid recovery. I have noticed the liability to recurrence of encephalitis, and a more severe attack in those cases, where there is a family history of insanity or mental instability, as though the toxin was possibly more severe in its effects on a brain already weakened by an hereditary taint.

I am, Sir, yours faithfully,
Robert H. Norgate,
Medical Superintendent, Southmead Hospital,
Sept. 29th, 1924. Bristol.

EXPERIMENT AND OBSERVATION.

To the Editor of The Lancet.

Sir,—In the introductory address by Sir David Ferrier published in The Lancet of Oct. 4th, a quotation from Lord Moulton, evidently endorsed by the speaker, occurs as follows: "The right way to advance knowledge is by experiment. When we are reduced to observation, science crawls." As a mathematician and chemist, the experimental method of advancing knowledge may have seemed to Lord Moulton the only method of importance. But it is unfortunate that this one-sided statement should be authoritatively presented to medical students, since of those who may feel a wish to advance their science perhaps nine-tenths will never get the chance of performing experiments either before or after they are qualified. They might also have been told that the extent to which advance depends on experiment varies with the sciences; that physics and chemistry exemplify sciences forwarded almost exclusively by experiment, while at the other extreme is a science like geology, built up almost entirely on observation and inference; that medical science occupies an intermediate position, experiment being necessary to determine causes and means of cure, while the observational method is necessary to differentiate and delineate disease. Patient and continuous observation of diseased subjects is the crying need of every generation in medicine; its neglect being due, not to its unimportance, but to the difficulties surrounding it, and because its importance is seldom taught in the schools. The insight given by successful observation is of signal importance to medical progress, and may even determine a new epoch in the study of a subject; the masters of this method have at all times been among the acknowledged eminent of their age. Every student should be made to realise that nothing in his training or after-opportunities need prevent him from embarking on a career of research, or from hoping to reap the distinction and reward of some solid discovery.

I am, Sir, yours faithfully,

Liverpool, Oct. 6th, 1924. EDMUND HUGHES.

THE NEW METHYLATED SPIRIT.

To the Editor of THE LANCET.

SIR,—Having to-day ordered a lotion containing spt. vini meth., I was told by the chemist to whom the prescription had been taken that there is some doubt whether this spirit, since the recent alteration in its composition, is suitable for application to the skin. Seeing how very largely it has been so used in the past, it is desirable to know certainly whether methylated spirit, in its new form, has any harmful action on the skin.

I am, Sir, yours faithfully,

Oct. 6th, 1924. SENEX.

*** The crude pyridine which since May last has been added in the proportion of 0·5 per cent. to methylated spirit as sold to the public is, we understand, irritating to the skin as well as to mucous membranes.—ED. L.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

R. M. Drennan to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. J. H. R. Bond retires on ret. pay and is granted the rank of Col.

TERRITORIAL ARMY.

Maj. P. J. Gaffikin to be Lt.-Col. and to commd. the 131st (Home Counties) Field Amb., vice Lt.-Col. C. W. Ponder, whose tenure of commd. expires.

Capt. G. Adam, having attained the age limit, is retired and retains the rank of Capt.

ROYAL AIR FORCE.

C. J. MacQuillan and F. P. Schofield are granted short service commissions as Flying Officers.

INDIAN MEDICAL SERVICE.

The King has approved the retirement of Maj.-Gen. B. H. Deare.

Lt. Ram Nath Bhandari to be Capt.

Lt.-Col. E. F. Tucker, on return from leave, becomes Senior Medical Officer, First Physician, J. J. Hospital, and Professor of Medicine and Therapeutics, Grant Medical College, Bombay. Lt.-Col. R. M. Carter becomes Second Physician and Registrar, J. J. Hospital, and Professor of Materia Medica and Pharmacy, Grant Medical College, Bombay. Maj. M. J. Holgate, on the termination of the Mahableshwar season, took over the duties of Surgeon, Ahmednagar. Maj. S. S. Vazifdar acts as Presidency Surgeon, Second District, Bombay, with attached duties, in addition to his present duties as Second Physician at the J. J. Hospital, until relieved of the latter duties by Lt.-Col. R. M. Carter, and thereafter acts as full-time Presidency Surgeon, Second District, Bombay, with attached duties. Lt.-Col. C. B. McConaghy has been posted as Administrative Medical Officer in Central India and Residency Surgeon, Indore. Maj. A. N. Thomas, on return from leave, has taken over the duties of Superintendent of Mahableshwar, vice Maj. M. J. Holgate.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Reassembling of Parliament.

PARLIAMENT reassembled on Tuesday, Sept. 30th, after the summer recess. The object of having an earlier meeting than was originally intended was to pass the Irish Boundary Bill, a measure giving power to the British Government to set up the Commission to settle the boundary between Northern Ireland and the Free State, and to appoint a Commissioner in view of the refusal of the Northern Irish Government to do so.

HOUSE OF COMMONS.

THURSDAY, OCT. 2ND.

Revision of Pension Warrant, 1919.

Dr. SPERO asked the Minister of Pensions if he proposed to revise the whole of the Royal Pensions Warrant, 1921, in view of the large number of amendments and changes of entitlement which had been issued recently.—Mr. F. O. ROBERTS replied: Yes, Sir. It is intended at a convenient opportunity to issue an up-to-date version of the Royal Warrant of December, 1919 (to which I presume the hon. Member refers), and of the concurrent Orders-in-Council, embodying the various amendments that have been made since their issue.

Physical and Mental Condition of Murderers.

Mr. LAMB asked the Home Secretary whether official daily bulletins were issued as to the physical, mental, and spiritual condition of convicted murderers awaiting execution; and if not, whether he had taken any steps to ascertain the source of such bulletins that had recently been published.—Mr. DAVIES (Under Secretary for Home Affairs) replied: My attention has been called to bulletins or reports of this kind which have recently appeared in newspapers. They certainly have not been communicated by the prison authorities. The reports themselves have been utterly devoid of truth and seem either to have been invented by the writers or to have been based upon false statements made to them by discharged prisoners or others professing to be able to supply information.

Medical Opinion and the Smoke Nuisance.

Sir WALTER DE FRECE asked the Home Secretary whether he was aware of the growing criticisms of medical officers as to the evil effect of the smoke nuisance; and, seeing that the law was not sufficient to deal with this growing menace to the public health and that the police statistics showed a serious increase in the number of private chimneys which caught fire as the result of carelessness in respect of sweeping, would he inquire into the matter.—Mr. GREENWOOD (Parliamentary Secretary to the Ministry of Health) replied: A Bill dealing with the smoke nuisance has been introduced in the House of Lords and has been read a second time and passed through Committee. My right hon. friend is advised that powers already exist for dealing with the nuisance arising from private chimneys which take fire.

New Form of Death Certificate.

Mr. PENNY asked the Home Secretary whether, in the new form of death certificate to be issued, he would make it compulsory for doctors to inspect the body of the deceased before signing, so as to safeguard, as far as possible, against the chance of live burial.—Mr. GREENWOOD replied: No powers are available which would enable such an obligation to be imposed upon medical practitioners, and legislation would be necessary to give effect to the hon. Member's suggestion.

Procreation of Unfit Children.

Mr. BLACK asked the Minister of Health whether, in view of the continuously enlarging financial responsibilities accepted by the State with regard to unemployment, invalidity, and old age, he would state the policy of the Government with respect to the procreation of children who, owing to physical or mental deficiencies, became a charge upon the State funds; and whether he was prepared to appoint a Royal Commission to investigate into the possibilities of improving the calibre of the nation by restricting the procreation of children to persons possessing a recognised minimum standard of physical and mental efficiency.—Mr. GREENWOOD replied: As at present advised my right hon. friend does not see his way to recommending the appointment of a Royal Commission on this subject. I may perhaps add that he is not aware of the existence of any recognised standards of physical and mental efficiency.

Lee Commission and Indian Medical Service.

Colonel Sir CHARLES YATE asked the Under Secretary of State for India if it was now proposed to bring the recommendations of the Lee Commission into operation without further delay; and whether these recommendations would be adopted in full, including those relating to the medical service.—Mr. RICHARDS replied: I am not yet in a position to make any statement on this subject. My noble friend, the Secretary of State, is still in correspondence with the Government of India on certain points, and both he and the Government are desirous that orders on the report should be issued with the least possible delay.

Reform of Public Health Laws.

Mr. ROBERT RICHARDSON asked the Minister of Health if the statement in the Annual Report for 1923 of Sir George Newman to the effect that in hundreds of sanitary districts there was a failure to use the facilities which the sanitary law provided was based upon official records of the Ministry of Health; and, if so, whether he was prepared to appoint a Royal Commission to inquire generally into the whole question of the administration of the laws relating to public health and housing and the generally unsatisfactory conditions prevailing in the sanitary service.—Mr. GREENWOOD replied: The answer to the first part of the question is Yes. The second part refers to a matter which would fall within the scope of the terms of reference to the Royal Commission on local government now sitting.

Sir George Newman and Public Health Administration.

Mr. JOHN GUEST asked the Minister of Health whether he had read the statement of Sir George Newman in his report for 1923, to the effect that there were many authorities and medical officers of health who muddled on from hand to mouth, the victims of every passing whim or popular stunt, instead of organising their work as responsible and competent men charged with the duty of directing the public service of their district; whether there was any record at the Ministry of the muddling authorities and incompetent medical officers of health; and, if so, what action he proposed to take, in the interests of the community, to remove the medical officers of health referred to from office and to supersede such authorities.—Mr. WHEATLEY replied: The answer to the first two parts of the question is Yes. With regard to the third part, the difficulty is largely due to the passivity of local public opinion on health questions in many areas, and I have this point under consideration. Further difficulty arises owing to the number and size of many of the 1800 sanitary authorities, a subject which would fall within the scope of the terms of reference to the Royal Commission on Local Government now sitting. There is no question that the large authorities are, as a whole, discharging their duties satisfactorily.

Medical News.

UNIVERSITY OF LONDON: *University College.*—Prof. S. L. Rashkovich, M.D., Director of the Technical Sanitary Institute of Petrograd, will deliver a course of four public lectures on Water-supply and Its Purification, at University College, on Fridays, Oct. 10th, 17th, 24th, and 31st, at 5.30 P.M. The chair at the first lecture will be taken by Prof. H. R. Kenwood. Tickets of admission are not required.

UNIVERSITY OF LONDON: *Parliamentary By-Election.*—In his election address Dr. F. G. Bushnell says that he supports thoroughly the programme of the Labour Party to develop fully the medical and social "community services," especially the extension of the benefits of the National Health Insurance Acts, and the further and better utilisation of hospitals and infirmaries for the public. He believes in wide publicity and propaganda being afforded by the State in preventive medicine, and is in complete agreement with the Advisory Committee of the Trades Union and Labour Party in their health policy. The task of preventive medicine is made more difficult by the fact that most infections are due to ignorance of the principles of hygiene and sanitation. Preventive medicine, he concludes, has become a basic factor in sociology both as regards the unhealthy conditions that affect the person (i.e., hygiene) and those that result from defective environment (i.e., sanitation).

HOSPITAL DINNERS.—The Annual Dinner of the Old Students of the *London Hospital* was held at the Trocadero Restaurant on Oct. 1st. Over 200 attended, and the present and past staff of the hospital were well represented. The chair was taken by Prof. W. Bulloch, who for 27 years has been in charge of the bacteriological department of the hospital. He referred to the changes which had taken place in that time, during which the whole of the visiting staff has changed, with the single exception of Lord Dawson. Paying a striking tribute to Lord Knutsford, he spoke of the rapid developments which had been made at the London Hospital in his own time, contrasting its atmosphere of energy and progress with the "mediæval repose" which he had observed elsewhere. His hearers were left in no doubt as to the vast advances which have been made in scientific medicine, in which bacteriology has played so large a part, but some of them may have felt a twinge of regret at the passing of the personalities who dominated the hospital 30 years ago, when F. J. Smith astonished the students by his language, and Treves by his operative daring. In spite of its size, Prof. Bulloch concluded, the London Hospital had succeeded in maintaining that personal contact with its students which was one of its oldest traditions, and which formed the greatest and most striking characteristic of medical teaching in this country.

The Annual Dinner of the Past and Present Students of the *Middlesex Hospital* Medical School was held at the Hotel Cecil on Wednesday, Oct. 1st, Mr. G. Gordon-Taylor, surgeon to the hospital, occupying the chair. There was a very large gathering of the alumni of the school, the total, including guests, being about 260. The guests included Sir Douglas McGarel Hogg, M.P., Sir William Leishman, F.R.S., the Mayor of St. Marylebone, Mr. W. Hartman, and Mr. F. G. Hallett. The Chairman, in proposing "The Middlesex Hospital and its Medical School," referred to the friendly relations between the lay board and the medical staff and to their loyal coöperation in all matters affecting the work of the hospital. He alluded to the value of the efforts of the League of the Associated Hospitals of St. Marylebone and to the formation through the agency of the mayor of an employers branch of this League. He voiced the general regret at the loss of Lord Athlone as chairman of the weekly board, pointing out that he had endeared himself to every person connected with the hospital. The resignation of Dr. Campbell Thomson and that of Prof. W. S. Lazarus-Barlow were also serious losses to the hospital and school. He was sure that all present would be sorry to learn of the resignation of Mr. A. E. Webb-Johnson of the office of dean, which he had filled with such great advantage to the school, and he drew attention to the great work he had achieved in helping to put the school on a sound financial basis. He alluded to the pride felt by all Middlesex men in the re-election of Sir John Bland-Sutton to the office of President of the Royal College of Surgeons and to the professional honours and distinctions conferred upon other old students of the school. Mr. Richard C. Davis, chairman of the Finance Committee of the school, in replying for the hospital, pointed out that medical education and research were essential functions of a hospital. In spite of its great value research was not fostered in this country as it deserved to be. Mr. Webb-Johnson, in replying for the school, mentioned the generous gift of £20,000 from Mr. Courtauld to endow the chair of anatomy in the medical school. He thought it must be unique for a hospital to number amongst its residents at one time three gold medallists at the London M.B., as was recently the case at the Middlesex Hospital. He expressed his regret at relinquishing the office of dean, but regarded the charge of the school as in the nature of a relay race. Mr. C. Vincent Cotterell, in replying on behalf of the old students, described the great increase in the work of the hospital. When he joined 46 years ago the hospital had 305 beds with 36 devoted to cancer cases, whereas now there were 450 beds with 92 for cancer. He mentioned that out of a staff of 40, 26 were old students of the school. Mr. J. W. Nankivell, the senior Broderip Scholar, replied on behalf of the present students. The toast of "The Guests" was proposed by Sir Arnold Lawson. Sir Douglas Hogg, in replying, maintained that the efficiency and progress of medical science were due to the hospitals. He spoke with approval of the useful work of the St. Marylebone Hospitals League. Sir William Leishman spoke of medical research and of the useful work being accomplished in the Bland-Sutton and cancer research laboratories. He was optimistic as to the outlook in the future for pathological research.

The Annual Dinner of *St. Mary's Hospital* Medical School was held at the Connaught Rooms on Monday, Oct. 6th, when 149 members of the school, past and present, attended. Dr. Eustace M. Callender, who was in the chair, proposed the continued prosperity of the school, and contrasted St. Mary's in his day with the present position, recalling some amusing scenes of his student days. He asserted his belief that the future of the school was very bright, judging by the expansion of the buildings, the keenness of the teaching staff, and the large number of students. The Chairman of the Hospital Board, Mr. A. R. Prideaux, gave a short résumé of the activities of the hospital during the present year, and mentioned the extension of the X ray department and the proposed increase in operating theatre accommodation as instances of progress. He alluded to the great loss the hospital had sustained in the loss of Mr. W. H. Clayton-Greene from the surgical staff and paid a high tribute to his great position in the surgical world. Another loss which was Cardiff's gain was the appointment of Dr. E. H. Kettle to the professorship of pathology and bacteriology in the Welsh National University. He laid stress on the extraordinarily cordial relations which continued to exist between the lay board and the consulting staff of the hospital, a state of affairs so essential to the prosperity of any such institution. Dr. C. M. Wilson, Dean of the Medical School, stated that the entry was still maintained at a high figure, and held out great hopes for the future. Sir Anderson Critchett paid a graceful tribute to Dr. Callender, after whose reply the party broke up into informal groups to renew old friendships.

The annual Old Students' Dinner of *St. Bartholomew's Hospital* was held in the Great Hall of the hospital on Wednesday, Oct. 1st, when Dr. J. H. Drysdale presided for the last time as an active member of the honorary staff. In proposing the Hospital and College, he contrasted the pathological department as it existed 30 years ago, when the late Prof. A. A. Kanthack occupied one small room, with the present position when it had outgrown the handsome building quite recently provided. He alluded with satisfaction to the new building on the opposite side of Giltspur-street, which was now efficiently serving the purpose of teaching and research in physiology, physics, and pharmacology. Sir Herbert Cohen, joint treasurer of the Medical College, and Dr. Morley Fletcher replied, the latter reminding his hearers that although the new department had been paid entirely out of students' fees as a result of the large entries after the war, it remained true that no medical school could now pay its way solely out of such fees. Sir Archibald Garrod proposed "Our Guests," to which response was made by Mr. C. J. Ritchie, master of the Merchant Taylors Company, and Sir Walter Fletcher, who characterised the physiological equipment as second to none in London hospitals, and alluded to the further supplies of radium placed by the Cancer Campaign at the disposal of the hospital. The toast of "The Chairman" was proposed with grace and feeling by Mr. W. T. Holmes Spicer.

The annual dinner of *St. George's Hospital* was held on Oct. 1st at the New Hotel Metropole, London, Sir Isambard Owen, consulting physician to the hospital, being in the chair. There was a good attendance of students, and the feature of the dinner was the favourable report made by the Dean, Dr. J. A. Torrens, on the position of the medical school. The entry at the school, he said, bade fair to be larger than it had been for some 25 years, so that St. George's Hospital would again be able to take its prominent place among the London schools, despite any numerical restriction implied by the reception only of students ready to enter upon their clinical work. The financial statement of the treasurer, Lord Greville, was also more favourable than many of the hearers had expected, though, as with many of the hospitals, a deficit, he feared, would have to be faced during the next year. Sir Isambard Owen's health was given by Sir Squire Sprigge, who outlined the great part in the development of the education of the country which had been played by Sir Isambard Owen in his work at the Universities of Wales, Durham and the Newcastle Colleges, and Bristol. The proceedings closed by the thanks of the company being extended to the secretaries of the dinner and with an impromptu appendix in the form of an amusing speech from Dr. W. S. Fox.

The *King's College Hospital* Past and Present Students' dinner was held on Oct. 1st at the Connaught Rooms. The chair was taken by Mr. Charles P. Childe, F.R.C.S., who was supported by Viscount Hambleden (chairman of the committee of management), and by many members of the honorary staff of the hospital. The gathering included over a hundred members of the school drawn from many different school years. The Chairman, in proposing the toast of "King's College Hospital," delighted his audience with reminiscences of his student days at the old hospital. He told of the many slums and landmarks in the neighbourhood (from which the old hospital drew its clinical material), which had now been swept away and replaced by the fine buildings adjacent to the Kingsway Estate. In those days King's occupied a high position in both work and sport, and the speaker, by a comparison of the activities of those days with the achievements of the past few years, showed that these traditions were being worthily maintained. Viscount Hambleden, in responding, assured the company that the student spirit was still there, and that it was extraordinarily alive on some occasions. He announced the decision of the Council of King Edward's Hospital Fund for London to pay off the remainder of the building debt on the hospital, which amounted to £16,000, and to contribute during the next five years the sum of £15,000 for the purpose of opening 40 fresh beds. Fourteen beds had been added already, and in November another complete ward of 26 beds would be reopened. The remainder of the evening was devoted to the renewing of old friendships. The success of the dinner was due to Dr. Ernest Playfair and Dr. Godfrey de Bec Turtle, who carried out the arrangements.

Westminster Hospital Old Students' Dinner.—On Thursday, Oct. 2nd, the first old students' dinner since the reopening of Westminster Hospital was held in Oddenino's Restaurant, Regent-street, W. The chair was taken by Sir Edward Pearson, chairman of the House Committee, and the assembly numbered over 100. In giving the toast of "The Hospital and the Medical School," the Chairman commented on the bright outlook for the future of the hospital, which last year had seemed somewhat gloomy. The hospital was now open again with new equipment and extra beds, and private wards had been adopted as part of the alterations. He paid a tribute to the work of the treasurer and of the Dean, Dr. A. S. Woodwark. The Chairman emphasised the advantages of a small medical school in keeping the staff and the students in close touch with one another. Dr. Woodwark replied. Dr. Hildred Carlill then proposed "The Past and Present Students," and in the course of his speech he made the gratifying announcement of a gift to the School of Medicine from his uncle, Mr. A. J. H. Carlill, of £20,000 towards the establishment of a pathological unit to commemorate the late Dr. J. B. Carlill, father of the donor. The offer was made conditionally on the school obtaining assistance from the University Grants Committee of the Treasury comparable with that afforded to units of medicine and surgery established elsewhere and on the school obtaining also the approval and coöperation of London University and the consent and support of the House Committee of Westminster Hospital. Dr. H. B. Brackenbury replied to the toast on behalf of the past students, and Mr. Rubra spoke for the present students. "Our Guests" was given by Mr. E. Rock Carling and responded to by Sir Robert Hudson. Mr. William Turner proposed "The Chairman." Among those present were Sir H. Mallaby Deely, Mr. H. J. Waring, Dr. Ainley Walker, Mr. A. E. Marshall (chairman of the Medical School Committee), Sir James Purves-Stewart, Sir H. Bryan Donkin, Sir F. de Havilland Hall, the Rev. Costley White, Sir J. Wormald, Mr. W. G. Spencer, Dr. S. Monckton Copeman, and Mr. George Cowell.

University College Hospital.—The dinner of the Past and Present Students of University College Hospital, which was postponed, is to take place on Friday, Oct. 24th, at 7.30 P.M., at the Hotel Cecil. Tickets can be obtained from Mr. Gwynne Williams and Prof. T. R. Elliott at the Medical School.

LONDON HOSPITAL MEDICAL COLLEGE.—The University Scholarship in Anatomy and Physiology (value £75), open to students of the Universities of Oxford and Cambridge, has been gained by Mr. J. G. A. Davel, of Trinity College, Oxford. The Epsom scholarship (free medical course) has been awarded to Mr. C. E. H. Turner.

ROYAL INSTITUTE OF PUBLIC HEALTH.—A course of nine lectures on the Health of the Commonwealth will be delivered in the lecture hall of the Institute, 37, Russell-square, London, W.C. 1, on consecutive Wednesdays at 4 P.M., commencing Oct. 15th. The first lecture will be given by Sir William Milligan on Physique in Relation to National Efficiency, and announcement of the others will be made in our Medical Diary. The Harben lectures will be delivered by Prof. E. L. Collis on Nov. 24th, 25th, and 27th, at 4.30 P.M. He will deal with Phthisis and Industrialism (National and Occupational), with reference to other infectious diseases. All who are interested in medico-sociological problems are invited to attend these lectures.

SCOTTISH BOARD OF HEALTH CONSULTATIVE COUNCILS.—The Scottish Board of Health have made the following new appointments to their several consultative councils: (1) Medical and Allied Services: Prof. J. R. Currie, University of Glasgow; Mr. A. Gofton, F.R.C.V.S., Chief Veterinary Inspector, Edinburgh; Dr. G. R. Livingston, Dumfries; and Prof. B. F. Watson, University of Edinburgh. (2) National Health Insurance (Approved Societies' Work): Mr. J. G. Barry, Glasgow; Miss Jean Coutts, Aberdeen; and Miss Jobson Stirling. (3) Local Health Administration and General Health Questions: Bailie P. J. Dollan, Glasgow; Mr. A. Findlay, Aberdeen; Mr. Hugh Fraser, Inverness; Bailie Simon G. Fraser, Dundee; and Mr. M. A. Reynard, Clerk to Parish Council, Glasgow. (4) Highlands and Islands: Mr. J. G. MacDonald, Inverness; and Mr. Hugh Miller, Stornoway.

RETIREMENT OF DR. E. W. HOPE.—In an announcement of his impending resignation (THE LANCET, Sept. 6th, p. 501) some account was given of the great work done by Dr. Hope for public health in general and for the City of Liverpool in particular. At a meeting of the

Liverpool City Council on Oct. 1st the Health Committee officially reported Dr. Hope's resignation, and a resolution was passed recording the Council's appreciation of the excellent services at the health department rendered by him for 40 years, during 30 of which he was medical officer of health. In proposing the resolution, Sir Archibald Salvidge described Dr. Hope as one of the most valuable public officials that Liverpool or any other corporation in the country had ever possessed. He has been consulted by many Royal Commissions and Government departments, and the French Government has conferred upon him the Order of Officier de l'Instruction Publique. Dr. Hope, we learn, is at present retaining the chair of public health at the University of Liverpool.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.—The new biochemical department of the hospital will be open for inspection on Thursday, Oct. 23rd, at 3 P.M., when visitors will also be free of the enlarged pathological laboratories and the wards of the hospital. There will be exhibits of scientific instruments in both departments.

MISSIONS TO LEPERS.—Mr. Robert J. Cochrane, M.B., Ch.B. Glasg., son of Dr. Thomas Cochrane, founder of the Union Medical College in Peking, an institution which the Rockefeller Foundation has now made one of the great medical colleges of the world, will be sailing shortly for India and the Far East in connexion with the growing work of the Missions to Lepers. He expects to study the methods of the Calcutta School of Tropical Medicine during the coming autumn in final preparation for world-wide specialisation in leprosy.

CHADWICK LECTURES.—The Chadwick Lecture programme for this autumn includes lectures in London on Defective Hygiene and Child-life, with special reference to the effect produced on growth and development of children by town dwelling and slum areas, by Dr. Lawson Dick; Rats, by Mr. Mark Hovell, F.R.C.S.; Smoke, with a review of its causes, its effects on vegetation, fabrics, masonry, and metal work, and its influence on health and the death-rate, by Prof. J. D. Cohen, F.R.S.; and Antenatal and Postnatal Child Physiology and Hygiene, by Dr. W. M. Feldman, F.R.S. Each lecture will be illustrated either by epidiascope or lantern slides, and among the chairmen will be Sir William J. Collins, chairman of the Chadwick Trustees, Sir James Crichton-Browne, and Sir Frank Baines. Further information about these lectures, which will be free to the public, may be obtained of the secretary, Mrs. Aubrey Richardson, O.B.E., at the offices of the Trust, 13, Great George-street, Westminster.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—The following scholarships have been awarded for 1924: *Entrance Arts Scholarships:* First (value £50), J. A. G. Bird (Cheltenham College); second (value £50), J. G. Dathan (Cranleigh). *Entrance Science Scholarships:* First (value £150), T. H. Wilson (Merchant Taylors' School); second (value £60), A. M. Easton (Whitgift Grammar School). *Entrance University Scholarship* (value £100): C. I. Tuckett (Rugby, and Trinity College, Cambridge); Proxime Accessit: V. B. Wigglesworth (Repton, and Gonville and Caius College, Cambridge). The William Tite Scholarship (£25) has been gained by H. C. Trowell (Reigate Grammar School).

The Old Students' dinner will take place at the Princes' Restaurant, Piccadilly, on Friday, Oct. 24th, at 7 P.M. for 7.30. The chair will be taken by Mr. Seymour Taylor, M.D., C.M. Aberd., F.R.C.P. Lond. The price of the dinner, inclusive of stewards' fee, is 15*s.*, to be paid at the Princes' Restaurant.

THE LATE MR. JOHN QUILLER ROWETT, LL.D.—The name of Mr. Rowett, whose death occurred under tragic circumstances on Oct. 1st, has been associated in the last few years with many lavish gifts to the cause of scientific research. Himself a business man, he had a deep sympathy with the advancement of many spheres of scientific work. His name will be remembered in connexion with the financing of the *Quest* expedition under Sir Ernest Shackleton. Most of all, however, Mr. Rowett's interests lay along the lines of medical and agricultural research. It was largely through his generosity that investigations were set going at the Middlesex Hospital—investigations which have already considerably advanced our knowledge of the origin of dental caries. At his farm in Sussex, Mr. Rowett carried out extensive researches in practical agriculture. His two interests were happily united in the founding of the "Rowett Institute of Research in Animal Nutrition" at Aberdeen. This institute consists of well-equipped biochemical, physiological, and bacteriological departments, together with an experimental farm. Scientific research in this country is the poorer for the untimely death of one who viewed it from an enlightened standpoint.

Sir Archibald Garrod has been appointed by the Home Secretary to be a member of the Advisory Committee on the Administration of the Cruelty to Animals Act, 1876, in the place of Sir Bryan Donkin, who has resigned.

Dr. J. F. E. Bridger, Principal Civil Medical Officer, has been appointed an official member of th Legislative Council of Ceylon.

HARVEIAN SOCIETY OF LONDON.—A clinical meeting of this Society will be held at the Paddingto Green Children's Hospital on Thursday, Oct. 16th, a 4.30 P.M.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The sittings of the Royal Commission on Nationa Health Insurance will be resumed on Oct. 16th. Any persons or bodies desiring to submit evidence are invited to communicate with the Secretary of the Commission, Mr. E Hackforth, Ministry of Health, Whitehall, London, S.W. 1.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Oct. 13th.

WAR: at 5 P.M.
Presidential Address:
Surgeon Vice-Admiral Joseph Chambers, R.N.: Hospita Ships in Peace and War.

Tuesday, Oct. 14th.

THERAPEUTICS AND PHARMACOLOGY: at 4.30 P.M.
Presidential Address:
Prof. A. J. Clark: "Quacks."

Wednesday, Oct. 15th.

HISTORY OF MEDICINE: at 5 P.M.
Presidential Address:
Dr. J. D. Rolleston: Bretonneau: His Life and Work.
Exhibit:
Mr. J. E. H. Roberts: Two (?) Presentation Copies o Wiseman.

Thursday, Oct. 16th.

DERMATOLOGY: at 5 P.M. (Cases at 4 P.M.)
Cases:
Mr. H. C. Samuel: Case for Diagnosis.
Dr. H. Semon: Sarcoid.
Dr. H. W. Barber: (1) Multiple Epitheliomata of the Ski (2 cases); (2) Parapsoriasis.
Mr. J. E. R. McDonagh: Xanthoma (Diabetic).
Paper:
Dr. Prosser White: Bakers' Eczema; a Clinical an Experimental Inquiry.

SOCIAL EVENING: at 8.30 P.M.
Fellows, Members of Sections, and their friends will b received by the President, Sir StClair Thomson, a 8.30 P.M.
Dr. W. T. Grenfell, C.M.G. (Labrador) will give a brie discourse on Medicine in a Corner of the Empir (with lantern illustrations) at 9.30 P.M.

Friday, Oct. 17th.

ELECTRO-THERAPEUTICS: at 8.30 P.M.
Presidential Address:
Dr. Stanley Melville: "Taking Stock."

MEDICAL SOCIETY OF LONDON, 11, Chandos-street Cavendish-square, W.
MONDAY, Oct. 13th.—8 P.M., Annual General Meeting. 8.30 P.M., Ordinary Meeting. Dr. E. M. Callender: President's Address on Medical Memories.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
Lecture arranged by the FELLOWSHIP OF MEDICINE and open to all members of the medical profession. Friday, Oct. 17th, 5.30 P.M.: Cancer of the Bladder, by Mr. J. Swift Joly.—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C. Special Intensive Course in Laryngology, Rhinology, and Otology, beginning on Monday, Oct. 13th.—BETHLEM ROYAL HOSPITAL, St. George's-fields, S.E. Lecture Demonstrations on Tuesday and Thursday, at 11 A.M., by Dr. Porter Phillips and Dr. Thomas Beaton.—LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Endsleigh-gardens. Tuesday and Thursday, Clinical Demonstration on Tropical Medicine, at 2 P.M., by Dr. G. C. Low and Dr. Manson-Bahr.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

Saturday, Oct. 18th.—4 p.m., Sir Archibald Garrod: Harveian Oration.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

Friday, Oct. 17th.—5 p.m., Prof. Arthur Keith: Museum Demonstration: Specimens illustrating Evolution of the Human Heart.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, Oct. 13th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 p.m., Dr. Scott Pinchin: Medical Out-patients. 2 p.m., Mr. Bishop Harman: Eye Dept.

Tuesday.—11 a.m., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 2 p.m., Mr. Sinclair: Surgical Out-patients.

Wednesday.—12.15 p.m., Dr. Burnford: Medical Pathology. 2 p.m., Dr. Owen: Medical Out-patients. 2 p.m., Dr. Pernet: Skin Dept.

Thursday.—11 a.m., Mr. Simson: Gynæcological Ward Visit. 12 noon, Medical Registrar: Clinical Methods. 2 p.m., Mr. MacDonald: Genito-Urinary Dept.

Friday.—10 a.m., Mr. Simson: Gynæcological Operations. 12 noon, Surgical Registrar: Surgical Pathology. 2 p.m., Mr. Vlasto: Throat, Nose, and Ear Dept.

Saturday.—9.30 a.m., Dr. Burnford: Bacterial Therapy. 10 a.m., Dr. Saunders: Diseases of Children. 10 a.m., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 a.m. to 6 p.m., Saturdays, 10 a.m. to 1 p.m., In-patients, Out-patients, Operations, Special Departments.

KING'S COLLEGE HOSPITAL LISTERIAN SOCIETY.

Wednesday, Oct. 15th.—8.30 p.m., Inaugural Address at King's College Hospital by Prof. Sir StClair Thomson: Shakespeare as an Aid to the Art and Practice of Medicine.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS POST-GRADUATE COURSE, Victoria Park, E.

Monday, Oct. 13th, to Friday, Oct. 17th, mornings and afternoons.

Wednesday.—3.30 p.m., Dr. A. Goodman Levy: (*a*) General Anæsthesia in Tuberculosis; (*b*) the Significance of Cyanosis in Pulmonary Disease.

Friday.—2 p.m., Lantern Lecture, Dr. Clive Riviere: Artificial Pneumothorax Treatment and its Complications.

HOSPITAL FOR SICK CHILDREN, Great Ormond-st., W.C.

Thursday, Oct. 16th.—4 p.m., Dr. Harrison: Interpretation of Sugars.

ST. JOHN'S HOSPITAL, Leicester-square, W.C.

Tuesday, Oct. 14th.—5 p.m., Dr. S. E. Dore: Physiology.

Thursday.—5 p.m, Dr. J. M. H. MacLeod: Morphology and Histopathology of Elementary Lesions.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 p.m.)

Week commencing Oct. 13th.—At the Children's Hospital: Dr. Murray Bligh: Common Forms of Mental Defect in Children, with cases. At the Southern Hospital: Dr. Macalister: Rheumatism and Some Rheumatoid Conditions. At the Northern Hospital: Dr. Cunningham: Pernicious Anæmia. At the Stanley Hospital: Mr. Heaney: Circulatory Diseases of the Extremities. At the Royal Infirmary: Mr. Litler Jones: Surgical Cases.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

Tuesday, Oct. 14th.—4.15 p.m., Dr. A. Ramsbottom: Differentiation of Anæmias.

Friday.—4.15 p.m., Prof. R. B. Wild: The Treatment of Pain.

ROYAL INSTITUTE OF PUBLIC HEALTH, Russell-square, W.C.

(Course of Lectures on the Health of the Commonwealth.)

Wednesday, Oct. 15th.—4 p.m., Sir William Milligan: Physique in Relation to National Efficiency.

Appointments.

Mussen, A. A., M.D. Dub., D.P.H. Camb., has been appointed Medical Officer of Health for the City of Liverpool in place of Dr. E. W. Hope, retired.

Overton, Sibyl Gertrude, M.B., B.S. Lond., D.P.H., an Inspector of Factories and Workshops.

Webb, Beatrice, M.D., Medical Officer to the Women's Training Department, University of London.

Wells, A. Q., M.B., B.Ch. Oxf., Certifying Surgeon under the Factory and Workshop Acts for the Eyam District of the county of Derby.

Manchester Royal Infirmary: Newell, R. L., F.R.C.S. Eng., Surgical Tutor; Hickson, S. K., M.B., Ch.B. Manch., M.R.C.P. Lond., Second Medical Registrar; Kahn, Miss, M.B., Ch.B. Manch., Clinical Assistant.

Vacancies.

For further information refer to the advertisement columns.

Birmingham, Queen's Hospital.—Third P. for Out-patients. £50.

Bristol Royal Infirmary.—Hon. Dermatologist and Hon. Asst. S. to Ear, Nose, and Throat Dept.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Res. H.S. £75.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. for six months. £62 10s.

Durham County Council Education Committee.—Asst. Sch. M.O. £600.

Durham, Richard Murray Hospital, Blackhill.—Res. M.O. £400.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Morning and Afternoon Cas. O.'s at rate £120. H.S. at rate £125. Also Res. M.O. £200.

Gloucestershire Mental Hospitals, Coney-hill, Barnwood.—Jun. Asst. M.O. £350.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Asst. Res. M.O. for six months. £75. Also H.P. £50.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Med. Reg. £100.

Johannesburg, S. African Institute for Medical Research.—Bacteriologist.

London Hospital Dental School, E.—Hon. Anæsthetist.

London Temperance Hospital, Hampstead-road, N.W.—Med. Reg. 40 guineas.

Manchester Babies Hospital, Burnage-lane, Levenshulme.—Res. M.O. for six months at rate £125.

Metropolitan Hospital, Kingsland-road, E.—Sen. H.P. and H.S., Jun. H.P. and H.S., two Cas. O.'s for six months. Each £50. Also Asst. P.

Monmouthshire County Council.—Two Asst. M.O.'s. £500.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Anæsthetist. £25.

Queensland Government.—Director of Laboratory of Microbiology, &c., Dept. of Public Health, Brisbane. £750.

Royal Chest Hospital, City-road, E.C.—P.

Royal Free Hospital, Gray's Inn-road, W.C.—Med. Reg. £250.

Royal Naval Medical Service.—Surg. Lieuts. 25s. per day.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Hon. S. and Hon. Gynæcologist for Out-patients.

St. Thomas's Hospital.—Pathologist. £500.

Stoke-on-Trent, North Staffordshire Infirmary.—Jun. H.P. £125.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Cas. O. and R. £150.

Wednesbury, Borough of.—M.O.H., &c. £800.

West Ham County Borough, Dagenham Sanatorium.—Asst. Res. M.O. £350.

Westminster Hospital, Broad Sanctuary, S.W.—P. for Dis. of Children.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Mevagissey, Cornwall; Westbury, Wiltshire; Haworth, Yorks (W.R.).

Births, Marriages, and Deaths.

BIRTHS.

Bridge.—On Sept. 29th, the wife of Capt. G. A. Bridge, M.C., R.A.M.C., Southsea-terrace, Portsmouth, of a daughter.

Jones.—On Sept 17th, the wife of W. Henry Jones, M.B., B.S. Lond., South Hackney, of a son.

Judson.—On Sept. 28th, the wife of Dr. J. E. Judson, of Portscatho, Cornwall, of a son.

Spong.—On Sept. 15th, at Exmouth, the wife of Major W. A. Spong, R.A.M.C., of a daughter (stillborn).

MARRIAGES.

Harries—Dickson.—On Sept. 30th, at St. Paul's Church, Bournemouth, Ivor Ewart Harries, M.R.C.S., L.R.C.P. Lond., to Norah Constance, younger daughter of Colonel W. D. Dickson, J.P., and Mrs. Dickson, of Southill, Dean Park, Bournemouth, formerly of Kildimo House, Co. Limerick.

Knowles—Inman.—On Oct. 1st, at Christ Church, Hampstead, Squadron-Leader R. H. Knowles, M.D., D.P.H., Royal Air Force, to Gladys Eyre, youngest daughter of Mr. and Mrs. Henry Reid Inman, The Grange, Hampstead Heath.

Ramsey—Jarvis.—On Sept. 25th, at Oadby Parish Church, Leicester, George Alexandar Ramsey, M.D., of London, Ontario, to Elsie Clara, daughter of Mr. and Mrs. W. G. Jarvis, Clivedon, Manor-road, Leicester.

Soady—Hugo.—On Oct. 1st, at the Church of the Holy Cross, Crediton, Devon, William Henry Soady, L.R.C.P. & S.I., of Crediton, to Gladys Katherine Hugo, only daughter of the late Edward Hugo, M.R.C.S., L.R.C.P., of Gillingham, Kent.

Wilson—Braxton Perres.—On Oct. 1st, at Marylebone Parish Church, Ronald Edmund Wilson, M.R.C.S., L.R.C.P., to Rosaleen Helen, younger daughter of the late Robert Braxton Perres, of Staplers, Isle of Wight.

DEATHS.

Baker.—On Oct. 4th, at Ceely House, Aylesbury, John Charles Baker, M.B., M.R.C.S., late Surgeon Captain, 2nd Bucks Battalion, O. and B.L.I., aged 62 years.

Harper.—On Oct. 4th, at Adrian-square, Westgate-on-Sea, Robert Russell Harper, L.R.C.P. Lond., M.R.C.S. Eng., in his 71st year.

Parkin.—On Oct. 1st, at Carnaby Chalet, Cardigan-road, Bridlington, Alfred Parkin, M.S., M.D. Lond., F.R.C.S.

Russell.—On Oct. 4th, at Downview-road, Worthing, George Ireland Russell, M.R.C.S., L.S.A., of Gravesend and N. Zealand, in his 86th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

"HEALTH WEEK."

"HEALTH WEEK," which is just over, would now appear to have become an established institution. As in previous years, the opportunity was taken of calling the attention of the general public to some of the more fundamental principles of health. The Health Week Committee issued for the occasion a number of "sermonettes," or rather texts for sermons, on such topics as coal smoke and health, with notes on the Public Health (Smoke Abatement) Bill now before the House of Lords; the Sunlight League formed in May, 1924; the value of fruit and vegetables; the care of the teeth, and so on. Education of public opinion on these and similar matters is apt to be a somewhat slow process, but the committee wisely insisted on the value of health teaching in schools. It may be recalled that at a conference of headmasters, held last December, a resolution was passed to the effect that it was desirable that some systematic teaching on the subject of hygiene should form part of the instruction of every boy and every girl during their time at school, thus laying a solid foundation in health knowledge for the whole nation. The efforts of the Health Week Committee, under the chairmanship of Prof. A. Bostock Hill, are deserving of the cordial support of the medical profession.

During the week Mr. Arthur Greenwood, M.P., Parliamentary Secretary of the Ministry of Health, gave an address at Stepney in which he attributed the considerable decline in the general death-rate and especially in the infant mortality-rate in recent years to the work of the public health service. He stated that during last year the amount of sickness and disablement amongst insured persons for which benefit was paid totalled 20½ million weeks or 394,000 years. Unemployment due to sickness was no less than a third of the unemployment arising from bad trade. Over twice as much time was lost last year through sickness as from industrial disputes. And even these appalling figures did not disclose the whole truth as they did not include the first three days of sickness for which no benefit was paid, nor the sickness amongst uninsured workers, and they omitted the loss of working power owing to premature deaths.

NEW OPEN SPACES FOR LONDON.

IN THE LANCET of Sept. 20th, p. 609, we commented on the broader outlook that is being taken from the health point of view with regard to London's parks and open spaces, and evidence of further progress in this direction comes from the work of the Metropolitan Public Gardens Association. At a meeting of this Association on Oct. 1st, at Denison House, Vauxhall Bridge-road, the Earl of Meath, the chairman, presiding, it was stated that the Open Spaces Bill promoted by the Association and other bodies had passed second reading in the House of Commons, and that a Bill to extend powers to plant trees in arterial and other roads had been introduced by the Ministry of Transport. A report was received that the laying out of Princes-square, Stepney, to which the Association largely contributed, had been completed and that the ground had been opened to the public. It was stated that Middlesex County Council had granted £5000, the balance of the amount required towards the purchase of 31½ acres of woodland at Ken Wood. Progress was reported in regard to schemes to acquire as public open spaces areas on Shooters Hill and Streatham Common, also the laying out and opening of Boston Manor Park, Brentford. Attention was drawn to the proposed removal of Bethlem Hospital from its present site in Southwark, and it was regarded as most important that steps should be taken to secure at least some portion of its site for public use.

YEAR-BOOK OF SCIENTIFIC AND LEARNED SOCIETIES.

WE received some time ago from Messrs. Charles Griffin and Co., Ltd. (Exeter-street, Strand, London, W.C.), a copy of the fortieth annual issue of the Year-book of the Scientific and Learned Societies of Great Britain and Ireland (389 pages, price 15s.). This is a record of the work done in science, literature, and art during the session 1922–23 by numerous societies and Government institutions, compiled from official sources. It was hoped when the year-book was founded 40 years ago that it would become in time the trusted desk-companion of the scientific worker as well as of the industrialist (in the widest possible sense) who wished to keep in touch with the advances made in his particular industry; this aim has been rendered possible by setting out from year to year the titles of papers read before scientific institutes throughout the kingdom. Such a list is of value in showing the direction which current research is taking, and the reader will not be led astray by errors or omissions, for on every page of the year-book is the mark of careful and thoughtful editing. We have greater confidence in making this comment as the book has intentionally lain on the library table for a number of weeks in order to test its accuracy and comprehensiveness. It is the more indispensable now that the Joint Board of Scientific Societies, after a brief existence, has ceased its operations. Conducted on its present lines this year-book will continue to fill a useful place on the shelves of the reference library.

OBSTINATE CONSTIPATION.

To the Editor of THE LANCET.

SIR,—I should be grateful if any of your readers would suggest appropriate treatment for the following case. The patient is a boy, aged 3 years, with a history of chronic constipation. He has recurrent rises of temperature and at times the rectum is prolapsed. Patient has been in the habit of taking two tablespoonfuls of liquid paraffin per day, but obtains a motion only every other day. He has now been put on a mixture containing sod. sulph., tr. bellad., and infus. sennæ, three times a day, before food. He is also given Nujol twice a day and one teaspoonful of cascara cordial at night. Abdominal massage has also been tried, but the bowels are still obstinate and prolapse recurs at times.

I am, Sir, yours faithfully,
CLINICAL.
Oct. 6th, 1924.

EMOTIONAL ARREST OF HÆMORRHAGE.

To the Editor of THE LANCET.

SIR,—An instance of what I take to be secretion of adrenalin as a result of stimulation by anger or fear may prove of interest to some of your readers. Whilst on a wild-fowling holiday in Ireland recently, I had a conversation with a gamekeeper who was apparently in great demand locally as a trimmer of fighting-cocks. Part of this trimming consists in cutting the comb—a process attended by considerable hæmorrhage. As soon as the comb is cut, the practice is to bring another fighting-cock near the first, when in most cases the bleeding stops. He added that, if the bleeding did not cease, the opinion was formed that the bird in question would never make a fighting-cock owing to lack of "spirit."

I am, Sir, yours faithfully,
SPORTIVUS.
Oct. 6th, 1924.

GREEN APPLES.

To the Editor of THE LANCET.

SIR,—With reference to your article last week discussing the cause of colic following the consumption of green apples, I think the mechanical theory there outlined must be substantially the correct one so far as unripe fruit goes. Much of the pain of dyspepsia is located in the pylorus, and the passage of hard lumps of material of any sort through the pylorus causes the characteristic "cannon-ball" sensation; the same sensation is often experienced when a duodenal tube is being passed. Green apples would, of course, be very difficult to disintegrate; the same fruit when cooked has no such effect, so that the pain must be the result of mechanical and not chemical condition of the food. The question might arise, "Why do not green apples cause pain in all cases?" The answer is that the motility of the pylorus and its sensitivity are not always the same. The best condition for pain would be a highly motile and sensitive pyloric canal. Usually these two would go together. The same applies to the intestine.

I am, Sir, yours faithfully,
C. LOVATT EVANS.

Physiological Laboratory, St. Bartholomew's Medical
College, E.C., Oct. 6th, 1924

AN UNGRATEFUL PATIENT.

A SOUTH AFRICAN correspondent informs us that at the Barberton Criminal Sessions, Transvaal, on Sept. 11th, a native named Sebob Fanee was sentenced to death for murdering a native witch doctor named Magesa, and Magesa's son, aged 10. As a motive for the crime it was asserted that Fanee resented a request by the witch doctor for a beast in payment of doctoring services rendered. It was also stated that another witch doctor and his wife had instigated the crime.

Burns.—It is difficult to say why the use of ambrine in the treatment of burns has almost died out. One reason may be that to get good results it is necessary to carry out a special technique, perfectly simple, but still special. It is easy to heat the stuff too hot and so make things worse than they were. Its ideal use is where there is a large series of cases to deal with, all of which can be treated in exactly the same way.

D. A. H.—So far as we know, there is no institution in London where treatment of cardiovascular cases is given on strict Nauheim lines. Such a clinic existed before the war, where this and other forms of physical treatment were administered under medical supervision. Various forms of effervescing bath are available for home use.

The Evolution
OF
NEUROLOGY AND ITS BEARING ON MEDICAL EDUCATION.

A Presidential Address to the Neurological Section of the Royal Society of Medicine, delivered on Oct. 9th, 1924,

By E. FARQUHAR BUZZARD, M.D. Oxf.,
F.R.C.P. Lond.,
PHYSICIAN TO ST. THOMAS'S HOSPITAL.

The approach to a presidential chair, which, if it could speak, would claim among its past occupants such men as Hughlings Jackson, David Ferrier, Victor Horsley, W. H. Gaskell, Sherrington, and Head, to name but a few of the most illustrious, is necessarily attended by a sense of inferiority difficult to reconcile with the pride of being chosen to fill such a position. The sense of inferiority is in no way mitigated by finding myself following directly in the footsteps of Dr. James Collier, whose successful term of office has just expired, and whom I always gratefully regard as my first neurological guide and teacher. It was my good fortune to find him in residence at Queen-square when I went there as a clinical clerk five-and-twenty years ago. In those days his boundless energy was only equalled by his unremitting patience, his willingness to impart knowledge, and his power of imbuing others with some of his own enthusiasm. We all know how tenaciously these characteristics have clung to him throughout the intervening years.

But the initiate at Queen-square of that time had more than enough to stimulate his enthusiasm. Every afternoon there were rounds with Hughlings Jackson, Bastian, Horsley, Gowers, or Ferrier. Mornings were spent note-taking in the wards and spare hours, often spreading far into the night, were devoted to work in the pathological laboratory under the safe guidance of Batten. It is no matter for surprise that we found the climate of Bloomsbury exhilarating and came to regard the hospital as a neurological Olympus. The gods have mostly left us, but their shrine remains as a monument to their labours and an inspiration to all pilgrims who pass that way.

In choosing my subject I have been largely influenced by recollections of the delights and difficulties of those days and by the desire, long entertained, to compare them with the conditions now governing the work and outlook of those on the threshold of our profession. Although comparisons are reputed to be odious, they may not be always uninstructive, and the present can never afford to neglect the lessons of the past. It is necessary, therefore, to my purpose to recall not only the actual work on which neurologists were engaged at the end of the last century, but the immediate aims and objects of their task. It will be necessary, too, to contrast these with our work and objectives of to-day and finally to consider how this comparison affects the problem of medical education.

For reasons which it would be superfluous to recite, my argument will be based on the development of neurology, but, if sound, it must apply with equal force to that of the whole of internal medicine. I hold that neurology is the eldest of the medical ologies, not perhaps by right of primogeniture, but because of its exceptional precocity. This precocity arises from the fact that even in infancy its anatomical elements were more readily cemented together by physiology than was the case with any other branch of medicine with the result that, contrary to all accepted ideas, its problems have become progressively more straightforward and easier of solution than those of its brethren. In other words, the science of neurology is approaching exactitude in regard to the relationship of symptoms and physical signs to disorders of function and changes in structure.

Aims and Objects of Nineteenth Century Neurology.

During the last quarter of the nineteenth century the edifice of neurology was in process of construction. Those engaged on the task were busy finding the necessary stones, labelling them and placing them, perhaps haphazard, in some kind of position. The foundations were chiefly composed of anatomical facts interspersed with meagre physiological details by way of mortar. The superstructure gradually grew in height as disease after disease was named and laid in place, but in the absence of any considered, draughted plan the architecture was faulty and lacking in proportion or design. A scientific edifice never attains completion, and this one has proved no exception to the rule. It has constantly called for renovation and repairs, in the course of which there has been much demolition and reconstruction. Here and there an arch has withstood the test of time, but many have rotted under exposure or sunk beneath the weight of experience. Nevertheless, we can be proud of our edifice, incomplete as it is; its foundations are of the right material, and every year sees them widened and solidified by additions to our knowledge of nervous anatomy and physiology.

In the days to which I have referred neurologists were, for the most part, collectors. Their interest was largely absorbed in finding and cataloguing undiscovered diseases, much as an entomologist or stamp collector seeks and classifies new specimens. The records of the Neurological Society testify to this enthusiasm, and probably the evolution of neuropathology has only followed that of all other sciences. The zeal for collecting precedes and breeds the spirit of inquiry.

The Altered Outlook of To-day.

And thus have time and increasing knowledge altered our outlook. The completed article in the shape of disease, even if it be a new specimen, inspires comparatively little interest in the minds of many of us, unless it throws light into the dark corners of pathology. Our collection lies neglected on the shelf and, if something is added to it, the addition is made with little pride. We have come to realise how small is our knowledge of health and healthy living function, and how imperative it is to recognise the smallest deviation from normal structure and function if we are to understand the natural history of disease, and to solve the problem of its prevention or frustration. This change is well illustrated in the proceedings of our section, as it is in those of other sections, and contributes in no small degree to the anxieties of our secretaries. Material for meetings and discussions is scarce. We are digging among roots deep in the ground, not merely culling the blossoms on the surface. The work is laborious, the soil requires careful sifting, and the buried treasure needs expert handling and critical inspection before it is ready to be appraised.

The history of ill-health now means much more to us than the unhealthy patient, and when unravelled is more helpful to us, and indirectly to the unfortunate sufferer, than prolonged contemplation of the ravages produced by disease. The latter may be easily detected by the eye of the trained observer; for the former we have to depend not only on our own skill in cross-examination but on the veracity, memory, and intelligence of others. In no branch of medicine has this truth been more strikingly displayed than in that of psychopathology, although it applies with equal force to every form of organic disorder. Unfortunately, perhaps as the result of faulty training or perhaps for economic reasons, its vital significance has not yet been grasped by the bulk of our profession.

To apply a sporting analogy to our past and present conceptions of morbid processes and our ways of dealing with them, we might compare the earlier one with golf and the later with cricket. The golf ball is an article provided, painted, and marked for us, and placed stationary in front of our eyes to hit. A physician may miss it; a surgeon may slice it; only a quack may drive it out of bounds or into a hazard without penalty. The cricket ball, hidden at its origin, comes from a distance and is deceptive in its flight. Its swerve, length, and break require watching, and the danger of complications and sequelæ in the shape of fieldsmen must be avoided if the wicket is to remain intact. Prolonged experience of the bowler's wiles may enable the batsman to play the ball with increasing confidence, but the danger of being bowled, stumped, or caught out can never be very far away. Surely we need more cricketers and fewer golfers in our ranks!

But the aspect of medicine has altered in other ways than that of perspective. Hard lines are disappearing, values are being rectified, and better composition is leading to improved grouping of its elements. In its early days a specialised off-shoot, like neurology, is apt to be isolated from its fellows; only as it approaches maturity is its complete dependence on the main trunk and close relationship with all other branches clearly determined. Thirty years ago neurologists were engrossed with clinical pictures and morbid anatomical specimens carefully preserved and mounted. A list of symptoms, a bedside photograph, and an elaborate series of microscopical slides served to illustrate and schedule a disease. Now it is to biochemistry, to bacteriology, to endocrinology, or to psychology that we look for light and understanding. Scarcely a day passes without the desire for a more intimate knowledge of the anatomy and physiology not only of the nervous system, but of every organ forming part of the human frame. Our thoughts are centred on the problems of pathogenesis, and the field of our inquiry extends far beyond the limits of our speciality.

It is not my intention for one moment to depreciate the work which has been done in the past or even to cavil with the inevitable course of events. In no other way could our knowledge have accumulated as it has done in the last 50 years, and no one could have foretold the course and direction of the paths and by-paths which are now to be traced on the map of medicine. But the time has come when this map requires careful reconsideration from the point of view of the medical student and medical education. It has become a maze rather than a map, a maze from which innumerable superfluous names and countless blind alleys must be eliminated in order that the main roads may stand out clearly for the student of medicine to see and follow.

NECESSARY REVISION OF THE MEDICAL CURRICULUM.

As an examiner I have been appalled at the amount of material which the examinee is expected to ingest and assimilate, and as a teacher I have become more and more convinced that our whole medical curriculum requires revision. Assuming that there has been, during the past 25 years, a great change and advance in our conception of disease, such as I have attempted to indicate, can it be said that our system of education has been modified to meet the situation? To some extent it has, but chiefly by way of patchwork and excrescences. Insistence on the importance of a particular speciality has led to a set period of time being devoted to its study, and the multiplication of these courses leaves the student no time to view medicine stereographically or to realise that principles rather than isolated facts are what he requires for his professional equipment.

In my own time I was taught physiology and anatomy, passed an examination in these subjects, forgot practically all I had learned, and started on new subjects called medicine and surgery. Three years' work, during which I learned much about disease and little about health, enabled me to pass another examination and qualify. A year later my steps were turned to Queen-square and my thoughts to neurology. Although I knew enough about nervous diseases to qualify, I very soon found that I had to go back to the beginning of things, re-learn the anatomy and physiology of the nervous system, and so gain, what was to me, an entirely new conception of the relationship between health and disease. As time passed one realised that this conception was one which was applicable not only to neurology, but to other branches of medicine, and that expert knowledge of the latter required the same close acquaintance with their particular aspects of anatomy and physiology.

Does the student of the present day, coming fresh to hospital wards or at the time of qualification, go through an experience which is very different? I think not. It is true that he is better trained in physiology and that his knowledge of this subject is more applicable to human life than the amphibian physiology on which I was brought up. But it is true also that the 25 intervening years have added enormously to the burden which his memory is called upon to bear. Has the divorce between physiology and anatomy, on the one hand, and medicine and surgery on the other been really annulled? I doubt it. We find the student who has recently passed a stiff examination in the former subjects confronted, for example, with a paralysed patient. He may be able to describe the bony ridges where certain muscles have their origin and insertion, even tentatively to suggest their nerve-supply, but of their function and the methods of demonstrating or investigating that function he is more often than not entirely ignorant. He knows nothing of agonists or antagonists, and muscular synergism, which he brings into play every hour of his life, has no meaning for him. He cannot describe the mechanism by which he adopts or maintains the erect position. He may be able to write a respectable essay on reflex action, but he is quite incapable of eliciting the normal reflexes from a healthy human subject.

He may recite with accuracy the muscles supplied by the oculo-motor nerve, but accommodation, convergence, and pupillary reactions are terms which convey but little anatomical or physiological significance to his mind. He has no familiarity with normal heart sounds, nor has he learned the difference between voluntary and involuntary respiration. He has read descriptions of the retina, but has never seen the fundus of an eye. He has used his voice since infancy, but has never seen a larynx in action. And yet all these gaps in his knowledge, and many others besides, do not belong to medicine or surgery, but to human anatomy and physiology.

In other words, after two or three years of studying anatomy and physiology he comes to us without any intimate knowledge of normal standards as applied to the living human being and without, therefore, the necessary data which would enable him to detect variations from the normal. And yet in the next two or three years he has so much to fill his time that there is little or no opportunity to make up this deficiency, with the result that he qualifies on such acquaintance with mature disease as is required of him and remains more or less ignorant of health and uncertain of detecting early disorders of function.

THE GOAL OF MEDICAL EDUCATION.

It may not be out of place to attempt a definition of the goal at which we all aim, or perhaps at which we ought to aim in medical education. What is the equipment which we would like to see possessed by every newly-qualified practitioner of medicine? In the first place he should be familiar with health as represented by normal structure and function, recognising, of course, that the latter are capable of considerable variations in respect to particular individuals or particular organs. In the second place he should have at his fingers' ends, and be able to carry out, all the ordinary tests employed in medicine for detecting variations from normal function. He should, for instance, be able to detect a flaw in the function of the pyramidal system, an inadequacy of renal function, or a deficiency on the part of the thyroid gland with some degree of alacrity and confidence.

In the third place he should be thoroughly acquainted with morbid processes, whether of degenerative, vascular, inflammatory, or neoplastic origin, and capable of recognising the alterations in structure which they produce. Fourthly, and this is perhaps he most important part of his equipment, he must be ntimate with the natural history of disease as illustrated by its clinical course. Lastly, he should be well grounded in the established *principles* of reatment, realising, as we must, that therapeutic measures are very unstable and dependent largely on he vogue of the moment.

For many years the student, in order to qualify, has been required to display a superficial knowledge of a number of named diseases, hastily acquired for he purpose of his examination. Examples of many he may never have met with, and his second-hand knowledge of them will have evaporated long before hey cross his path. I doubt whether any of you would disagree with me if I assert that under our present system very few newly-qualified men are dequately equipped for the practice of medicine. Fortunately, perhaps, only a minority assume really esponsible positions without passing through some ind of apprenticeship. If this is the case, I submit hat a system which has more regard for educating tudents in the essential principles of the science of medicine, and pays less attention to their knowledge f particular diseases, would provide the qualified ractitioner with sounder foundations on which to uild from experience.

When I spoke of revising the medical curriculum was referring to that period of time, five or six ears, now occupied chiefly by the study of anatomy, hysiology, organic chemistry, medicine, and surgery. The fundamental change which appears to me necesary is to remove the line of demarcation at present eparating the three former subjects from the two atter. The aim of education, put very shortly, is to imulate the natural functions of our higher cerebral evels, especially that function which enables us to ecognise similarity and difference, to distinguish soft om hard, sweet from sour, solid from fluid, square om round, smooth from rough, near from far, head om tail, good from bad, white from black, truth from alsehood, and normal from abnormal. How is it ossible to appreciate the soft, the square, the white, he truth, or the normal if we are not brought into ontact with the hard, the round, the black, the alse, or the abnormal? It is contrary to all rinciples of education as laid down by nature or xperience.

From the moment that the student enters upon the udy of anatomy or physiology he should feel that e has passed the threshold of medicine and surgery, hat he has begun his life's work, the study of the uman mind and body with all the vagaries and ills o which they are heirs. From the beginning he should e faced with living as well as dead subjects, and while is primary objective should be to learn all that is nown about normal structure and function, his task hould be made easier by opportunities for comparing he normal with the abnormal.

To take one example from the field of medicine. he study of the musculature should embrace not only he origin and insertion of muscles, their relationship o other structures and their nerve supply, but their ving function, the daily or hourly uses to which hey are put, and the methods by which their action inaction can be demonstrated. The student should ave the chance of observing at the same time—that to say, within a few hours or a few days—the limb e has dissected, a healthy living limb in action, and mbs which are paralysed as the result of lower and pper motor neurone lesions. In this way he would apidly gain an understanding of muscular action, the fference between voluntary and involuntary movement, the difference between the loss of muscle and the ss of movement, and of many simple reflex actions. or the moment the nature of the disease from which he paralysed patient suffers would not concern him. aving seen the normal and the abnormal side by side the features of each would remain fixed in his mind. He would still need his text-book of anatomy by his side, but he would stimulate his interest and solidify his memory by reading such books as Beevor's "Croonian Lectures on Muscular Movements" or Mackenzie's "Monograph on the Action of Muscles." It should not be difficult to arrange that at the same time he should be taught some neuro-muscular physiology, and become acquainted with the microscopical alterations of structure associated with Wallerian degeneration and muscular atrophy.

What applies to the musculature applies equally well to other tissues or organs. The teacher of anatomy should see that no student leaves him unfamiliar with the use of the ophthalmoscope or with the appearance of the fundus oculi. The teacher of physiology should be equally insistent on a clear understanding of the significance of diplopia and the principles underlying errors of refraction, their detection and analysis. The technique of test-meals and blood examination belong to the same department and offer similar opportunities to the student for acquiring the ability to differentiate between what is healthy and what is unhealthy.

But the expansion of anatomy and physiology does not end here. Radiology is a modern science which should be utilised early in the medical curriculum for the purpose of teaching. Long before the student comes to the wards he should be able to recognise a normal pituitary fossa from its bony outline, or a normal heart from the size and shape of the mobile shadow it casts on a screen. A series of barium meals demonstrating the normal and abnormal activities of the gastro-intestinal tract in the human subject would stimulate a live interest such as is unobtainable from the contemplation of dead abdominal viscera in the dissecting room. In short, no teacher can afford to neglect any method by which structure and function can be viewed from additional standpoints. The more sensory associations a subject can arouse in the human mind the clearer are its features and the more true is its perspective.

Mention of the human mind reminds us that the study of psychology should also begin during the physiological era of the medical curriculum. The greatest difficulties with which the practitioner is going to be confronted will be of psychological origin, and it would be well that his attention should be directed to this aspect of his work at the earliest opportunity. The study of the anatomy and physiology of the nervous system would lose none of its interest if it were associated with the digestion of a primer such as MacDougall's "Physiological Psychology."

It is not within my province to elaborate in greater detail than I have done the methods by which the student might be better educated during the first half of the five or six years of his curriculum nor to draw up any kind of time-table covering that period. I would submit, however, that when the day arrives for him to enter the wards of a hospital and to become an integral part of a medical unit or firm, he would be better equipped for the work which still awaits him before he has to face his qualifying ordeal.

Moreover, the training he has undergone should help to solve the great problem with which we, as teachers, are faced. What are we expected, or what do we hope, to teach students in the meagre period of six months allotted to the medical wards? At present we are obliged to spend much time in demonstrating what is normal in the structure and function of the living subject, in teaching how normal structure and function may be made manifest by methods as far apart as that for the preparation of a blood film and that for the elicitation of a knee-jerk. Instruments such as the stethoscope, laryngoscope, ophthalmoscope, and sphygmomanometer are placed in untrained hands and, with one exception, hardly ever reach terms of familiarity with their owners. The power of observation and the manual sensibility so necessary to the clinician have scarcely been brought into being, much less developed, so that even gross abnormalities in bodily conformation escape the student's eye or hand.

The Student's Work in His Final Months.

How little time is left over for those subjects which properly belong to these six months, which demand every moment the student can spare to them, and proficiency in which he can only acquire under the conditions of intimacy with patients appertaining to work in the wards. And what are the proper uses to which the six months should be devoted? In the first place, the student must utilise his daily opportunities for increasing his acquaintance with what is normal and abnormal in structure and function by bedside observation and laboratory research. If he has previously acquired some degree of familiarity with this aspect of his work he will be in a position to make the most of these opportunities. In the second place, he must now enter upon the study of the natural history of disease, a knowledge of which can only be acquired by the most assiduous attention to stories of ill-health, by probing their accuracy, and by attempts to give them their true interpretation. There is no part of medical work the significance of which needs more insistence on than that of history-taking. It requires endless time and patience, and the fact that it has hitherto been a task allotted to a period already overcrowded has meant that only a small proportion of students enter the profession adequately versed in the art, or appreciative of its paramount importance. That students are brought into contact with so much advanced disease in hospital wards and see so little of its early manifestations has often been urged, not without some justification, as a flaw in our system. But the significance of early manifestation would be lost without a first-hand knowledge of later developments, and the features of early manifestations can nearly always be elicited by careful history-taking.

There are two other lessons to be taught and learned during the period spent in the wards. It is the student's chance of acquiring the art of handling patients, using the term in its psychological as well as its physical sense, an art which must be taught by example rather than by precept, and one which is mastered by some men and women much more readily than by others. Finally, principles of treatment require exposition together with such detailed therapy in relation to the more common ailments as can be taught in the time at our disposal. An intelligent grasp of therapeutical principles is far more valuable than a profound knowledge of pharmacology. If the physician achieves success in regard to these four aspects of his teaching it is as much as he can expect, and success would come his way more frequently and more easily if the student were prepared for his lessons by previous training on the lines I have indicated.

As with internal medicine so it would be with the special departments. Already familiar with the methods by which the eye, the ear, and the throat are brought under inspection and able to detect variations from the normal the student would be ready to study the natural history of morbid processes as well as the physical signs and symptoms to which they give rise.

In the rough sketch which I have drawn for you of what I, and I believe many others, would regard as a forward step in medical education, there is much outline and little detail. The proposed alterations in teaching would necessitate some change in the point of view of examiners. Those conducting final examinations would need to satisfy themselves that candidates were adequately educated rather than replete with facts, and that their knowledge of medicine and surgery was built on foundations of physiology and anatomy sufficiently strong to support the additions which post-graduate experience would add to it year by year. There is no doubt that this describes the attitude of many examiners of to-day, but the examinee is still in the unfortunate position of having to prepare for questions on rare diseases concerning which his knowledge is only of text-book origin. His burden is heavy enough without this additional charge.

Evolution of Neurology in Relation to Medical Education.

It has been my endeavour to show that the proposed changes in medical education are the natural outcome of the lesson taught by the evolution of neurology, illustrated by a comparison of the work on which neurologists of 25 years ago were engaged with that of the present generation. The research of to-day depends for its success, in most instances, on an increasing intimacy with the anatomy and physiology of the nervous system and demands, consequently, a high standard of proficiency in these subjects from any member of the profession who chooses this branch of medicine as his speciality. Other branches are rapidly following the lead, with the result that a form of education better suited to the needs of the day, and more in consonance with our modern conception of pathology will soon be a matter of general demand.

The plea which I have made here is not a new one. It has been the subject of appeals more eloquent than mine and of much consideration in the minds of many who have never voiced their opinion. We are slow to adopt radical changes in our methods, but this change is rapidly becoming not only a necessity but inevitable. Inevitable because the progress of medicine demands from its disciples a higher standard of education, and better weapons with which to face ignorance, superstition, and prejudice as well as disease. It is often said, perhaps with a suspicion of apology, that medicine is an art, not a science. Is it for that reason that in the past we have been almost encouraged to forsake the sciences of anatomy and physiology when we begin to practise the arts of medicine and surgery? There is no need for such estrangement since all arts are based on science and lose neither their beauty nor their interest when science guides their practice.

The day is surely coming when we shall be proud to call ourselves scientists, but it will not dawn until we see physiology and anatomy walking hand in hand with medicine and surgery forming an ever-growing intimacy such as we can discern in the evolution of neurology.

SOME OBSERVATIONS ON THE "MODERN THEORY" OF RENAL SECRETION,

WITH AN ACCOUNT OF A CASE OF RENAL GLYCOSURIA.

By A. P. THOMSON, *M.C.*, M.D. Birm.,
M.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM;
PHYSICIAN TO OUT-PATIENTS, THE CHILDREN'S
HOSPITAL, BIRMINGHAM.

The object of this paper is to show that certain observations that I have made do not entirely support the modern theory of renal secretion. This theory, as propounded by Cushny, presumes that when blood passes through the capillaries of the renal glomeruli an exudate consisting of water and all the crystalloid bodies of the plasma, in their respective proportions, is passed out into Bowman's capsule by a process of physical filtration, which is modified normally by such factors as blood pressure and flow, the osmotic tension of the colloids of the blood, and the permeability of the membrane covering the capillary tuft. To quote Cushny's words, "the glomerular filtrate is thus practically deproteinised plasma." As this glomerular filtrate is passed down the kidney tubule certain bodies—the threshold bodies—are re-absorbed by the tubule cells in definite proportions determined by their normal titres in the plasma. "No-threshold" bodies, such as urea, are rejected and can only escape by the ureter. The function of the kidney may be shortly defined as "the filtration of the non-colloid constituents through the capsule, and the absorption of Locke's fluid through the tubule cells."

According to this theory, therefore, in the normal person sugar as a crystalloid threshold body passes freely out into the glomerular filtrate in the proportion in which it exists in the plasma, and is re-absorbed by the tubule cells at a certain fixed and definite rate, no matter what the needs of the organism at the moment. The rate of this re-absorption, though normally fixed at the "optimum," may presumably be modified by drugs which affect the tubule cells, by the presence of an unabsorbable substance in the filtrate which exercises an osmotic tension contrary to the current of tubule cell activity and, finally, by the time during which the filtrate remains in contact with the tubule cells—that is, by the rate at which it passes along the tubules. Cushny suggests that during diuresis the urine will approximate more closely to deproteinised plasma, because the tubule cells will not have time to elaborate their secretion from the rush of glomerular filtrate.

The Theory Tested by Clinical Experiments.

It occurred to me that it might be possible in a measure to test this hypothesis if I could compare the rate of excretion of sugar in the urine with the rate of excretion of water in a fasting diabetic with a constant level of hyperglycæmia. In such a case, if the theory were true, it seemed reasonable to expect a definite correlation between these two factors, for the glomerular filtrate would contain the same constant percentage of sugar as the blood plasma, the amount of re-absorption by the tubule cells would vary mainly with the rate of passage of the filtrate, and the other factors affecting re-absorption (such as any substance increasing osmotic tension in the filtrate, or some affection of the tubule cells) would either remain constant or vary to a very slight degree in a fasting patient in bed. A suitable case was not easy to find, as the hyperglycæmia of most diabetics declines during starvation.

In August, 1921, E. S., a girl aged 10, was sent to me with severe diabetes. I took her into the private ward of the Children's Hospital. After the amount of fat in her diet had been gradually reduced she was starved. The period of starvation began at 6 in the evening; the blood-sugar was then 0·25 per cent. The specimen of urine passed when she woke the next morning was sugar-free; the next specimen, passed at 10 A.M., contained much sugar. The blood-sugar was still above 0·2 per cent. The starvation continued, and the same thing happened the next day; the early morning specimen was sugar-free—all other specimens contained sugar. The hyperglycæmia was untouched by three days' starvation and the prognosis was practically hopeless (as a matter of fact, the child died a month later). However, I resolved to make one more attempt to control the diabetes and to investigate the curious intermittent glycosuria.

TABLE I.—*Twelve Consecutive Specimens of Urine from 10.30 a.m., August 29th, 1921.*

Total urine (oz.).	Total sugar (grains).	Intervals (hours).	Water excretion (ozs. per hour).	Sugar excretion (grains per hour).
10	44·0	4½	2·2	9·8
12	47·0	4	3·0	11·7
8½	35·0	3	2·9	11·6
22½	59·4	12½	1·8	4·7
12½	47·0	5	2·5	9·4
7½	1·1	5½	1·4	0·2
5	0	4	1·25	0
12	0	9¼	1·3	0
12	18·5	5½	2·2	3·4
12	10·5	5	2·4	2·1
8	6·3	4	2·0	1·6
17	0	8½	2·0	0

For a period of three days, during which food was withheld for 48 consecutive hours, each specimen of urine was collected separately, measured, and its content of sugar estimated. The times at which the specimens were passed were carefully noted. It was thus possible to obtain an estimate of the average rate of excretion of water and sugar per hour. The actual figures were as given in Table I.

The blood-sugar was estimated twice; at noon on August 30th it was 0·15 per cent., at 5 o'clock on the following morning it was 0·18 per cent. Shortly after the second estimation a specimen of urine was passed which was sugar-free. It seems probable that the blood-sugar remained fairly constant during the period of starvation. It will be seen that the rate of excretion of sugar corresponds almost exactly with the rate of excretion of water, for the first 50 hours.

It seems to me that this may be reconciled with Cushny's theory. When a flood of water passed along the tubules during the day the cells, keeping steadfastly to their fixed rate of re-absorption, allowed some of the sugar to escape, the amount so escaping being directly proportional to the rate of flow; during the night, although the percentage of sugar in the glomerular filtrate was the same or even higher, the cells, having more time to act in the presence of a less rapid flow, re-absorbed all the glucose, and so the early morning specimen was clear.

I next investigated the correlation of the curves of the rate of excretion of sugar and the rate of excretion of water in several diabetics during their period of starvation under treatment. These curves were frequently parallel during the earlier part of the starvation period, when presumably the blood-sugar had not fallen very much, if at all, from its usual level. Cushny mentions this fact in support of his theory. It seemed likely that glycosuria disappeared after starvation as the proportion of sugar in the plasma (and glomerular filtrate) fell to such a level that, at the normal rate of travel of the filtrate down the tubule, the cells were able to re-absorb all the sugar in it. If this were really so it should be possible to reproduce glycosuria in a starving diabetic who had just become sugar-free by inducing a sudden diuresis with an associated increase of rate of flow of the filtrate down the tubule. I attempted this on many occasions, but never succeeded in reproducing any glycosuria recognisable by the ordinary clinical tests. So many factors need to be considered in this relation besides the instability of the degree of glycæmia towards the end of the starvation period, that I was unable to consider this evidence as directly contrary to the Cushny hypothesis; it was, however, distinctly surprising.

It was at this stage that the kindness of my colleague, Dr. L. G. Parsons, enabled me to investigate fully a case of renal glycosuria, of which the following is a short account:—

In December, 1921, towards the end of a period of three months' probation as a nurse, Miss H., an apparently healthy girl of 23, was found to be passing large quantities of sugar in the urine. Nothing abnormal could be detected on examination; she had no symptoms of any kind, no thirst, no polyuria, no wasting, and menstruation was normal. So far as the patient could remember she had had no illness of importance, and had always been regarded as a perfectly healthy girl. There was no family history of diabetes, but her paternal uncle had been refused life insurance some years previously on account of glycosuria. He has remained in good health since without restriction of his diet. Subsequent examination of the urine of the patient's father, mother, and brother showed nothing abnormal.

Miss H. was admitted to a side-ward of the General Hospital under my care in December, 1921. Dr. W. T. Hillier, clinical pathologist to the hospital, examined the urine and reported as follows: "It (1) reduces Fehling's solution; (2) is fermented by yeast; (3) gives osazone crystals which cannot be distinguished from those of dextrose; and (4) gives a colour reaction with orcein indistinguishable spectroscopically from that given by dextrose." On ordinary diet the separate specimens of urine all contained sugar which varied in amount from 2·5 per cent. to 5·5 per cent.; the majority contained about 4 per cent. The total urine passed in the day was usually about 35 oz. Di-acetic acid was never detected. The "starvation" level of the sugar in the blood was 0·06 per cent., and the curve obtained after ingestion of 50 g. of glucose by the mouth was normal. The patient was allowed to return to duty and continue her career.

In May, 1923, 18 months after the first tolerance test, blood-sugar estimations were again made after 100 g. of glucose by the mouth, with the following result: Starvation level, 0·06 per cent.; half an hour after glucose, 0·165 per cent.; one hour after glucose, 0·15 per cent.: two hours after glucose, 0·08 per cent. These values are within the limits of normal, but slightly higher than in December, 1921:

the dose of glucose was twice as large on this occasion, and I do not think there is any evidence of loss of tolerance, for I do not agree with MacLean that 50 g. of glucose by the mouth will always produce a maximal response in the blood-sugar of a normal person. Apart from occasional colds, the patient has remained well for nearly three years, and has carried out her duties satisfactorily. The total excretion of glucose remains about the same; during the tolerance test of May, 1923, the specimen passed two hours after taking the glucose contained 10 per cent. of sugar.

TABLE II. (*Miss H.*)—*Ordinary Diet.*

Total urine (c.cm.).	Total sugar (grammes).	Intervals (hours).	Water excretion (c.cm. per hour).	Sugar excretion (grammes per hour).

225	11·9	9·0	25·0	1·32

In December, 1921, for three days, while she was on ordinary diet, every specimen of urine passed was collected separately and measured and estimated in the same way as in the case of E. S., the diabetic child. (Table II.) A comparison of the rate of water and sugar excretion showed a correlation which was very close but not quite exact. Having regard, however, to the temporary disturbances of the blood-sugar level which occurred after the glucose and other meals, if at no other times, the correspondence is remarkable. During a period of 36 hours' starvation the glycosuria was unaffected and a similar relation of the rates of water and sugar excretion was noticed. Curiously enough, it was not as close as that shown during the days on ordinary diet. She was in bed throughout the whole period. (Table III.)

In February, 1922, the patient was readmitted for further investigation. I proposed to starve her for three days. On the second day I intended to limit the fluid intake to sips of water by the mouth, and on the third day to give her large quantities to drink in order to compare the rates of water and sugar excretion in the different conditions. Unfortunately, on the second morning of the investigation she became faint while getting out of bed, and during the day, as the result presumably of the starvation and the limitation of fluid intake, she became acidosed and it did not seem justifiable to continue the experiment. Diuresis was therefore induced towards the end of the second day and lasted only for a few hours. Estimations of the sugar, urea, and total chloride were made in each specimen of urine passed; the quantities were carefully measured and the times accurately kept. (Table IV.) The estimations of the blood-sugar at noon of the two days of investigation showed the same result, 0·08 per cent. It seems fair to assume that it remained constant, or nearly so, throughout the period. The rates of sugar and water excretion on the chart show fairly good correspondence until the forty-eighth hour. The chloride excretion is less accurately correlated, and that of urea tends to dissociation.

TABLE IV.

Date.	Time.	Interval (hours).	Urine (c.cm.).	Water excreted (c.cm. per hour).	Sugar (per cent.).	Total sugar.	Sugar excreted (grammes per hour).	Urea (per cent.).	Total urea.	Urea excreted (grammes per hour).	Chlorides (per cent.).	Total chlorides.	Chlorides excreted (grammes per hour).	Di-acetic acid.

When diuresis was fully established the quantity of sugar excreted in the urine fell very considerably. That the percentage of glycosuria should fall with diuresis was to be expected; that the total excretion should fall was surprising, and I am quite unable to reconcile this result with the Cushny hypothesis. Were the "modern theory" wholly true the result of diuresis would have been a smaller degree of elaboration by the tubules and consequently a greater total loss of sugar.

It may, perhaps, be suggested that the onset of acidosis vitiates the findings of this investigation, but I do not think so, for acidosis was well established at the twenty-fifth hour, and the curves of water and sugar excretion corresponded well with each other and with the modern theory until the forty-eighth hour—that is, until diuresis occurred. Again, it may be contended that the kidneys were pathological, and that it is not fair to apply the results of an investigation in pathology to what is essentially a problem in physiology. It seems to me, however, that in this patient the modern theory must presume either that the kidney tubules were unable to re-absorb sugar from the glomerular filtrate to the normal extent, or that the glomerular capsule during filtration at the normal rate exercised a selective function in the excessive excretion of glucose from the plasma. The latter suggestion is in itself improbable, and would be abhorrent to the upholders of the modern theory who deny any selective activity to the more highly specialised tubule cells. If the former suggestion be accepted I am at loss to explain why the tubule cells should so readily recover their power of re-absorption of sugar in the difficult circumstances of diuresis, and should lose it again when the glomerular filtrate passed slowly before them.

On March 14th, 1922, I approached the problem in another way. Over a period of five hours of induced diuresis hourly estimations of the hæmoglobin, sugar percentage, and total chloride percentage of the blood were made. At the same time hourly (in one instance half-hourly owing to the intensity of the diuresis) specimens of the urine were collected and measured, and estimations of the urea, sugar, and total chloride were made, with the results shown in Table V.

Clinical Observations Not Explained by the Modern Theory.

It will be seen that during diuresis the total quantity of sugar excreted in the urine diminished by comparison with the quantity excreted in the first hour when the rate of excretion was normal; that the excretion of urea was similarly reduced, but that the excretion of chlorides was, if anything, a little increased. The blood values for sugar and chloride remained practically constant; the hæmoglobin varied only once at the fifth hour to any extent. Unfortunately, estimations of the blood-urea were not made, the specimens having been lost. I had intended to compare the relative concentration in the urine of the no-threshold body urea and the threshold bodies, the chlorides, and sugar. As the data are insufficient, this comparison is not possible, but the main fact is unaffected that in this case, while the glycæmia remained constant, the amount of sugar excreted in the urine during diuresis diminished considerably. In my opinion, therefore, it is not possible to reconcile the results of my observations on these two cases of glycosuria in patients with a constant level of glycæmia with the modern theory of renal secretion as set forth by Prof. Cushny.

TABLE V.

Time.	Interval.	Fluid intake (c.cm.).	Urine excreted (c.cm.).	Rate of excretion of water (c.cm. per hour).	Blood sugar (per cent.).	Blood chlorine (per cent.).	Urine sugar (per cent.). 6	1	684	399	399	0·048	0·587	0·45	1·79	1·79	0·186	0·74	0·74	0·175	0·698	0·698	92

Speculation in a matter about which so little is known is attractive but rather idle. I would point out, however, that up to a certain point the result of the investigation appeared to support the "filtration and re-absorption" hypothesis, for during excretion of urine at a more or less normal rate, in both the diabetic and non-diabetic case, there was a remarkable correlation between the curves of the rates of water and sugar excretion. With the onset of diuresis in the second case, however, the correlation is entirely lost. Prof. Cushny writes ("The Secretion of the Urine," 1917, p. 194) as follows:—

> "Another difficulty is presented by experiments in which diuresis is superimposed on an existing phloridzin glycosuria, for if the amount of filtrate is increased while its sugar percentage remains unchanged and none of the sugar is re-absorbed in the tubules the total sugar of the urine must, of course, be augmented." (*Footnote.*—This actually occurs when diuresis is superimposed on the glycosuria of pancreatic diabetes and also in glycosuria in the rabbit from the administration of sugar.) "This is stated to be the case by Weber, while Loewe's experiments seem to be opposed to it. In order to substantiate this objection it would be necessary to show that the glucose concentration of the plasma is unchanged during the diuresis, and this has not been done."

Conclusions.

I think I may claim that my second case fulfils this condition, and that in my first case, although the blood-sugar estimations were not very numerous, there is strong presumptive evidence that the level of glycæmia remained fairly constant. It is true that my estimations were of the sugar in the whole blood and not solely of the concentration in the plasma, but it seems improbable that there would be sufficient alteration in the relative proportions of the sugar in the corpuscles and in the plasma during diuresis to account for the remarkable diminution in excretion.

It is not suggested that because my results in these cases are not to be reconciled with the "modern theory," therefore Prof. Cushny's views must be set aside completely. As I have already pointed out, my results, up to a certain point, are fully consistent with the filtration re-absorption hypothesis. It may well be that the modern theory tells a part rather than the whole story of renal excretion. For the time being I think it reasonable to accept the modern theory as correct during renal excretion at a normal rate. During diuresis induced by fluid by the mouth, however, some additional factor must be invoked besides filtration by the glomeruli and re-absorption of threshold bodies at a fixed rate by the tubule cells. What that factor is we do not know, but Hamburger's suggestion that the permeability of the glomerular membrane may be changed very considerably by an alteration in the constitution of the blood brought to it by the afferent arteriole has a great deal to recommend it. It seems that this alteration in permeability may be brought about by changes in the composition of the blood which are so slight that we are at present unable to detect them with certainty. There is other evidence that alteration of the permeability of the membrane may occur in the well-recognised fact that once glycosuria has been induced by taking glucose by the mouth it may persist for some hours after the glycæmia has fallen back to a normal or subnormal level. This condition is frequently found in the routine performance of tests of carbohydrate tolerance, and is often not associated with diuresis.

Finally, I have frequently observed that diabetics after a period of fasting will remain sugar-free with their glycæmia at a higher level than before the fast when they were passing considerable quantities of sugar in the urine. There is often no alteration in the total quantity of urine passed in these cases, and it is difficult to account for them on any other basis than that of a change in the permeability of the glomerular capsule.

It is with much pleasure that I acknowledge the valuable help of Dr. E. M. Ainscow, resident medical officer at the General Hospital, and of Dr. W. T. Hillier, the clinical pathologist, in the investigation of the second case.

SUBACUTE INFECTIVE ENDOCARDITIS.

A CLINICAL STUDY OF THIRTY CASES.

BY JOHN GRACIE, M.B., F.R.F.P.S. GLASG.,
SENIOR ASSISTANT PHYSICIAN, WESTERN INFIRMARY,
GLASGOW; VISITING PHYSICIAN, BELLAHOUSTON
HOSPITAL, GLASGOW.

THE modern realisation of the morbidity and mortality caused by heart disease has induced me to give some personal observation on the clinical manifestations of subacute infective endocarditis. The disease has for long been a recognised entity, but the clinical descriptions in the older text-books were somewhat vague, and as a result it was difficult to recognise and frequently missed. The disease is not uncommon, and I believe that one of the reasons which accounts for failure to recognise it is that, regarding it as an infective disease, a high remittent temperature associated with marked endocardial lesions is expected, and in the absence of a febrile temperature the progressive nature of the disease is liable to be overlooked. Sir Thomas Horder aptly described it as "a disease of great importance, partly on account of the difficulty attending its recognition, but still more on account of the difficulties attending its successful treatment."

I propose to deal with the disease as it has presented itself to me, describing its clinical characteristics as observed in a series of 30 cases which I have had under observation.

Age-incidence.

My cases have all (with two older exceptions) been in men between 25 and 35 years of age, who appeared to have been robust in early life—in fact, the majority of them had been on active service for several years in the late war. On referring to statistics I notice that 90 per cent. of cases were between 10 and 40 years of age, so that our proportion agrees in maximum age-incidence, and, while my opportunities of observing cases under 20 years of age have been limited, I believe that the disease manifests itself most commonly between the ages of 25 and 35.

Predisposing Causes.

In the case of pensioners, I have had great difficulty in eliciting a history of illness or disease prior to enlistment, but their subsequent history is easy to obtain, and the following are the diseases from which they suffered :—

Trench fever	8
Dysentery	5
Influenza	4
Malaria	4
Pneumonia	3
Wounds	2
Rheumatic fever ..	2
Enteric fever	1
Starvation	1

It will be observed that rheumatic fever takes its place towards the end of the list, but unwillingness on the part of the patient to acknowledge having suffered from it in early life probably accounts for this. Trench fever and influenza might be grouped together as preceding and probably predisposing diseases on account of similarity in symptoms and difficulties in accurate differentiation. In all cases the blood was examined for the Wassermann reaction. Only two gave a positive result, and both had suffered from other diseases—viz., malaria and enteric fever. It would appear, therefore, that syphilis need not be regarded as predisposing to this disease.

Symptoms.

General malaise ; feeling of exhaustion ; shortness of breath ; slight palpitation or rather consciousness of fast beating of the heart, more particularly on slight exertion ; tendency to sweat readily, and frequent night sweatings.

Signs.

Appearance of Patient.—Pallor of an even more pronounced type than that generally associated with aortic regurgitation is a characteristic feature, and it is present in cases which show no signs of an aortic lesion. This pallor should at once arrest attention, and should lead one to suspect an infective endocarditis. At a late stage there is a slightly yellowish tinge—café au lait tint. With the progress of the disease blood destruction increases and the hæmoglobin may fall to 20–30 per cent. There is a marked loss of flesh.

Pulse.—The pulse-rate is accelerated, generally 80–90 per minute, though frequently up to 100 or over. It remains persistently high, even when the patient is confined to bed. It is regular and of medium or low tension. Digitalis, though administered in large doses, fails to reduce the rate.

Temperature.—The disease being insidious in its onset, continued fever is not characteristic, and the slight variations of temperature which do occur are apt to be missed. If, however, the temperature is taken regularly, slight rises up to 99° F. will be observed. These generally take place in the evenings, and at intervals which vary from three to seven or more days. Those slight rises of temperature, in the absence of any other specific cause, should arouse suspicion as to the nature of the disease. In fact, a slight irregular intermittent fever, associated with a constantly accelerated pulse-rate and pallor, are of themselves sufficient to justify a provisional diagnosis of subacute infective endocarditis. Later, as the disease progresses, the temperature tends to be constantly subfebrile in character, but rarely exceeding 101°.

Heart.—All cases which came under my observation had affections of the mitral valve on admission, while a few had, in addition, evidence of implication of the aortic valves. Cases which came under observation at an early period showed little or no evidence of cardiac enlargement, but later, as the disease progressed, the area of cardiac dullness became enlarged, the enlargement being steadily progressive, and most marked in cases where the primary lesion was mitral. Terminally, the left border of cardiac dullness extended in one case to between the anterior and mid-axillary line. This patient had on admission a well-marked mitral regurgitant murmur, later a blurring of the second sound at the aortic area, and finally an aortic diastolic murmur. The extension of the disease from the mitral to the aortic valves, as evidenced by murmurs, was an interesting point in more than half of my cases, and it was accompanied by a gradual and definite enlargement of the heart. The aortic diastolic murmur was not due to a relative incompetence, but to actual organic changes in the valves, verified by post-mortem examination. Changes in the conductivity of the heart muscle also take place, the most common being bundle lesions and varying degrees of heart-block.

Spleen.—The next most common feature is enlargement of the spleen. I have come to regard splenic enlargement as an essentially characteristic sign. All my cases showed it. In 27 the spleen was definitely palpable, while in the remaining three the area of splenic dullness was decidedly increased. The enlargement was of a gradual and progressive nature, and it was never associated with sudden pain or other evidence of infarction. The spleen is, however, tender to pressure. It is possible that an infarct may take place in an already enlarged spleen, but I am convinced that it enlarges as a result of the infective process, as in typhoid fever or malaria. On post-mortem examination no infarctions were found in any of my cases, only a chronic hyperplasia of spleen tissue.

Lungs.—The respiratory-rate was accelerated, and in the early stages nothing was discovered on physical examination beyond a slight pulmonary catarrh. As the disease progressed, breathlessness became more marked, and signs of pulmonary œdema developed. Three cases showed signs of pulmonary infarction accompanied by a copious expectoration of blood and mucus. It is here worthy of note that the clinical picture is often that of obscure or latent tuberculosis. The sputum from two cases which were sent into hospital with a diagnosis of pulmonary tuberculosis was frequently examined and found negative. On post-mortem examination no evidence of tuberculosis was found in any organ. It is possible that the diagnosis of pulmonary tuberculosis was made on account of the evening rise of temperature, cough, pallor, and night sweating, although there were no signs of lung involvement.

Liver.—While the liver enlarges coincidently with, and in a somewhat similar manner to the spleen, the rate of enlargement is not marked until the terminal stages, it being as a rule congestive. In one post mortem the liver was an excellent example of "nutmeg liver."

Kidneys.—None of my cases had hæmaturia, though all had slight and transient albuminuria at some stage of their illness, a condition which became permanent in the terminal stages.

Clubbing of the Finger-tips.—This is very common. In cases of long standing definite clubbing, accompanied by lengthening and broadening of the terminal phalanges, develops. The finger-tips differ from those seen in congenital heart disease in being pale and showing no venous stasis.

Emboli.—Petechiæ are of common occurrence and are generally confined to the trunk. They would appear to be in part due either directly to the infective agent or to small emboli. In my opinion, they are of small diagnostic value. Emboli affecting the larger organs were not common. This may be accounted for by the fact that all my patients were under observation for a considerable time and confined strictly to bed.

Blood Cultures.—Bacteriological examination was carried out in ten cases, and only two showed any organisms. These were staphylococci of low virulence outside their normal habitat.

Case History.

The following notes on a case recently admitted to hospital illustrate the difficulty in diagnosis.

D. M., aged 25, had been acutely ill for 14 days prior to admission, but had not been well for some time previously, having suffered from shortness of breath and palpitation. Fourteen days ago he developed acute pain in the abdomen, and later marked breathlessness. Two days ago he noticed that his urine was dark red in colour and scanty, also that his face and legs were swollen. He had four attacks of rheumatic fever in early life. He was sent to hospital as a case of acute nephritis.

Condition on Admission.—Pulse, 100; resp., 40; temp., 97·2° F. He was extremely pale. His face was puffy, and there was some œdema of his feet and ankles. His skin was clear. His lungs were clear to percussion—a few moist râles were heard at both bases. His heart was enlarged to the left. There was a loud systolic murmur at the apex, and a slight diastolic murmur at the base. The spleen was palpable, and there was some hepatic enlargement. The kidneys were not palpable, and the bladder was not distended. No urine was available for examination. He died suddenly one hour after admission.

Post-mortem Examination.—Heart enlarged, evidence of old endocarditis, with subacute endocarditis affecting both mitral and aortic valves. Lungs: Evidences of slight venous congestion. Spleen: Much enlarged. Liver: Enlarged. Kidneys: Enlarged. Interstitial nephritis with capsule adherent in parts. Brain: No abnormality.

Post-mortem Diagnosis.—Subacute infective endocarditis.

Prognosis.

The disease, when once established, is invariably fatal. Periods of quiescence do occur, but they are generally of short duration, the patient as a rule dying of cardiac failure, or death resulting from embolism. Euphoria is often striking. Perhaps this is accounted for by the toxic process; at any rate, it makes the illness less distressing to the patient, who looks forward with hope to his cure.

Treatment.

I have tried various forms of treatment, and although some for a time gave encouraging results in that the patients stated that they felt better, none were permanently benefited. Some of the different forms of treatment tried were:—

(*a*) *Salicylates*, which appeared to benefit one case, the patient being alive ten months after discharge, and apparently recovered from an acute exacerbation of the disease.

(*b*) *Autogenous vaccine* was tried in one case but was of no value.

(*c*) *Mixed phylacogen vaccine.* Definite amelioration of symptoms, but of no permanent value.

(*d*) *Eusol intravenous injections* 50 c.cm. at a time. Patients became cyanosed, and complained of shortness of breath and considerable distress after the injection. The following day they felt much better, and there was a fall in the pulse-rate. This proved to be of a temporary nature. A second injection was given with the same result, but owing to the immediate distress following the injections, and the doubtful improvement, this treatment was discontinued.

(*e*) *Arsenic.* A Wassermann blood-test was made in all cases. Two gave a positive reaction, and each was treated with novarsenobillon some months prior to any evidence of the disease, and it would appear that this had no action in preventing its development.

(*f*) *Quinine salicylate*, gr. v.–x., thrice daily, appeared to have some beneficial action.

Prevention.

Owing to the failure of curative forms of treatment one naturally considers the possibilities of preventive measures. Diseases which are common in this country, and which I believe predispose to subacute infective endocarditis, are rheumatic fever, pneumonia, and influenza.

With regard to rheumatic fever, endocarditis has always been recognised as one of its chief complications, and on that account, as also on account of the tendency to relapses, patients suffering from the disease are confined to bed for lengthened periods. This, by giving the heart the maximum amount of rest, enables it to escape with the minimum amount of damage. True prophylaxis would be the removal of the causal agent, but this is difficult on account of uncertainty as to its nature. Attention should, however, be paid to the prevention of chill and damp at work, housing conditions, and the removal of septic foci in teeth, tonsils, &c. Whether homes of recovery for convalescents from rheumatic fever will ever be successful is questionable, at least the rheumatic child, who is often restless and fidgety, ought to be given a chance by strict confinement to bed. The case of the unfortunate man who has to do his work, or the housewife who has her duties to attend to, is more difficult to overcome.

It used to be said that patients who recovered from pneumonia did so "without any after-effects, and without cardiac involvement," but this cannot be regarded as an accurate statement. Of late years the tendency has been to shorten the period of convalescence, doubtless due to the desire of patients to get back to their duties. The older physicians, however, insisted on a prolonged period of convalescence, and this apparently justified their better prognosis. Now that it is a notifiable disease, it is to be hoped that many of the serious after-effects will be avoided with the better nursing and supervision in hospitals during the acute illness and convalescence. These remarks would apply equally to influenza. Both are toxic diseases, and although at the time there may be no endocardial mischief apparent, they certainly give rise to a weakened myocardium—a latent focus of disease may be established which, under provocation from some debilitating cause, will assert itself in the course of time.

The early controversy with regard to endocardial lesions resulting from trench fever would appear to support this view. It is now evident that those who contended that there were no endocardial complications based their opinion on early observations, while those who supported the opposite view did so from observations at a later stage—usually during late convalescence.

Summary.

The essential points in the diagnosis of acute infective endocarditis are: (1) pallor, (2) clubbing of finger-tips, (3) slight irregular intermittent fever, followed by afebrile intervals, (4) pulse-rate increased, (5) splenic enlargement, (6) valvular disease, (7) signs of embolism. A more prolonged convalescence and careful supervision of patients after acute illnesses are urged.

WOMEN ON HOSPITAL BOARDS AT LIVERPOOL.—A large and representative conference summoned by the Social and Industrial Reform Committee of the Liverpool Women Citizens' Association to discuss the question of the appointment of women on hospital boards was held recently in Liverpool. It appears that in a number of Liverpool hospitals, including the Royal, the Southern, and the Northern, there were no women on the boards, nor any special women's committees with powers. A resolution was carried unanimously to the effect that the presence of an adequate number of capable women on the boards or committees of management of the hospitals was desirable in the interests of efficient, economic, and sympathetic administration, and that the meeting noted with regret that a considerable number of Liverpool hospitals had no women on their managing boards, and resolved to work for the removal of this defect.

THE THERAPEUTIC EFFECTS OF ULTRA-VIOLET RADIATIONS.

BY C. LEE PATTISON, M.B., B.S. LOND.,
MEDICAL SUPERINTENDENT, KING EDWARD VII. HOSPITAL, SHEFFIELD, AND SURGICAL TUBERCULOSIS OFFICER, CITY OF SHEFFIELD.

ULTRA-VIOLET radiations can be obtained from the sun and from various artificial sources, but while the therapeutic value of insolation is now universally recognised, it is important to realise that *all* the benefits obtained by this method of treatment are not due to the effect of light.

Leonard Hill[1] has shown that the exposure of the naked body to cool air raises the basal metabolism from 50 to 100 per cent., and also that since the amount of moisture which cool air can hold is small, the effect of breathing it will be to cause a flow of secretion from the respiratory mucous membrane. These beneficial results are independent of any radiation effects and must not be confused with them. The value of "open-air" institutions is largely due to this increased metabolism caused by cold. The surprising way in which muscular tone and nutrition are kept good in patients who are confined to bed with their limbs fixed in appliances is explainable by the fact that such patients are continually shivering, and are therefore exercising their muscles. I have frequently found that the appetite and general condition of patients have been greatly improved by the production of shivering two or three times a day for short periods.

When considering the effects of ultra-violet radiation it is important to remember that no rays reaching us from the sun are shorter than 290 $\mu\mu$ in length. The rays from the carbon arc are more like solar radiations than those obtained from other sources, some of which, for example, the tungsten-arc and quartz-mercury vapour lamps, give out some very short rays. These may have a quite different physiological effect from the longer rays obtained from exposure to the sun.

So far as our present knowledge goes it would seem that there are two ways in which ultra-violet radiations may act beneficially: (1) by increasing the bactericidal power of the blood, and (2) by activating the vitamins in the body.

Increase of the Bactericidal Power of the Blood.

As a result of some interesting experiments it has recently been stated[2] that "Any insult to the skin, whether produced by ultra-violet and invisible rays, or by dark heat, or by blistering agents, appears to provoke or increase the defensive power of the body."

Probably the results are brought about in two different ways. (1) By warming the blood. This is caused by the absorption of the dark heat and the visible rays. Sonne proved that radiations by visible rays increased the resistance of guinea-pigs to diphtheria toxin, and others have brought forward evidence in support of the beneficial effect of heat in this direction. (2) By the absorption of the products of tissue damage acting as a stimulant to immunising mechanisms. Rays below about 300 $\mu\mu$ only penetrate a very minute distance through the skin. As stated above, there are no rays shorter than 290 $\mu\mu$ in solar radiation.

It seems likely, therefore, that this tissue destruction is only produced by the dark heat, visible and near ultra-violet rays, and of course, by blistering agents, &c. So far it would seem that of the ultra-violet radiations only those of the "near" region have any effect on immunisation. But other investigators claim that shorter rays have a greater chemical effect, and do penetrate the skin sufficiently to produce their results, provided that they are intense and act for some time.

Schunck[3] says: "It is certain that the radiations most effective in causing sunburn, irritation, and destruction of animal tissue are chiefly confined to the middle ultra-violet region," and that the greatest effect is between 235 $\mu\mu$ and 250 $\mu\mu$. Verhoef and Bell[4] carried out experiments which proved that it is the radiations shorter than 305 $\mu\mu$ which injure cells by chemical action. Burge[5] states that ultra-violet rays kill living cells by changing protoplasm so that certain salts can combine with it to form insoluble compounds; and that the effective radiation is between 254 $\mu\mu$ and 302 $\mu\mu$. Ultra-violet rays of short wavelengths convert oxygen into ozone, and it has been suggested that the formation of this in the superficial cells of the skin causes irritation and tissue damage. Colebrook[6] has recently shown that the bactericidal power of the blood is not always increased by ultra-violet radiations, but that in certain patients in which it is already low ultra-violet rays will depress it still further.

This will possibly be the reason why I have found that some patients get worse when treated with ultra-violet radiations. In all these cases I have noticed that the weight has decreased, and there is a marked loss of appetite and energy. Occasionally in children with osseous tuberculosis there has been an increase in activity of the local lesion, but this has not been so serious as the alteration in the general condition. Fortunately, the majority of these patients have regained their previous health rapidly on discontinuing the light treatment.

Effect on Vitamins.

Vitamin A (either alone or allied with some similar substance) has been shown to be an important factor in controlling the normal growth and calcification of the body.

Mellanby[7] has shown that ultra-violet light activates the fat-soluble A-vitamin already stored in the body, although it has no power of synthesising it, so that in this respect (in calcification and growth) ultra-violet radiation applied without giving vitamin A in sufficient quantity would have no beneficial effect. Miss Luce's work,[8] showing that the antirachitic power of milk is definitely increased if the cows be exposed to sunshine, affords additional evidence of the value of radiations in this direction. There is also some evidence that if air, through which ultra-violet radiations have passed, be breathed, a similar effect will be produced to that obtained by exposure of the skin to the rays. It is interesting to note in this connexion that Zwaardemaker[9] has shown that the place of potassium in Ringer's solution can be taken by radiations from radium, so far as regards maintenance of nutrition and function of a frog's heart.

Pigmentation.

I believe that the commonly accepted assertion that the degree of pigmentation is an indication of the resistance of the body to disease is wrong. It is, of course, well recognised that the complexion of the patient influences the amount of pigmentation; blondes pigment with difficulty and persons with red hair less easily still.

Apart from these primary differences I recognise at least three distinct types of pigmentation, which may occur irrespective of the complexion of the patient. (1) The dark reddish-brown colour, which later becomes an almost chocolate-brown—this follows exposure to the sun's rays and to radiations from a carbon arc lamp; (2) a slatey-grey colour which follows prolonged exposure to the rays emitted by the quartz-mercury vapour lamp; (3) various shades of yellow, rather similar to, but not to be confused with, the colour sometimes seen in cachectic patients. This form of pigmentation may follow the use of any source of ultra-violet radiation, and I have found it chiefly in patients who are not making satisfactory progress.

Any observer who has closely watched patients treated by artificial or natural heliotherapy, suffering from such a disease as bone tuberculosis, will have noticed that some of them with similar complexions will, under similar conditions, pigment much more than others, *irrespective* of the condition of their general health or local lesions. I have very frequently seen patients with well-marked deep brown pigmentation with actively progressing disease, and my personal feeling is that, apart from the yellow type mentioned above, the degree and type of pigmentation are no indication of the response of the patient to treatment.

THE USE OF PITUITARY WHOLE GLAND IN CHRONIC CONSTIPATION.

BY BERNARD MYERS, C.M.G., M.D. EDIN.,
M.R.C.P. LOND.,
PHYSICIAN TO THE CHILDREN'S CLINIC, MARYLEBONE-ROAD, ETC.

THE result of administering pituitary whole gland by the mouth in this case was so striking as to warrant a record being published.

The patient, a girl aged 14 years, was first seen by me early in January last year. She had suffered from constipation from birth, the bowels acting, as a rule, only once in seven or eight days. She looked very ill. The skin and her general appearance suggested a toxic condition. There was practically no colour in the cheeks and her lips were white. She possessed much less energy than most girls of her age and it required a great effort on her part to enable her to take any interest in things generally. The appetite was large, she slept fairly well, but was restless at night. There were a few glands in the right iliac fossa. Her net weight was 4 st. 9 lb. 10 oz., and her height 56 in. In her general appearance her mother stated that she took after her father. Constipation did not run in the family, but there had been a tendency to constipation with the mother throughout her life. The child had previously suffered from measles and whooping-cough, from which she had made excellent recoveries. When 3 years of age a motor-car ran over her, but apparently caused no injury. With regard to her bowels, the mother stated that her daughter went to stool each day but failed to have an action. She did not suffer from worms.

Treatment.—She was given mist. alba night and morning and this was effective for a time. Later on mist. mag. co. was tried with fair success. Tr. nuc. vom. benefited her in certain respects, but the constipation remained as before. Liquid paraffin proved distinctly useful, but a tablespoonful three times daily was necessary to ensure an action of the bowels, and even that did not always prove successful. On some days the paraffin was passed without fæces accompanying it. A month after she was first seen, a bismuth meal, and, later, barium injections per rectum showed some ballooning of the sigmoid and of the upper part of the rectum. The condition of the skeletal muscles was distinctly atonic, and the bowel seemed to be similarly affected.

After a further two months' trial on various laxatives, purgatives, and tonics, which merely opened the bowels with difficulty and did not in any sense alleviate the toxæmia, I determined to try the effect of pituitary whole gland to see if it would encourage normal contraction of the bowel. The effect of the subcutaneous injections of pituitary extract upon the bowel is well known, but it would be unthinkable that any patient should continue such injections for the rest of her natural life. For practical purposes, therefore, it would be necessary for the endocrine substance to be administered per os. One grain of pituitary whole gland (Armour) was administered thrice daily after meals, the liquid paraffin in small doses being continued. Apparently, as a result of this treatment, the bowels were now opened daily. The liquid paraffin was discontinued after a couple of weeks, but the pituitary whole gland was continued. The bowels have continued to be opened daily by this method up to the present time. The mother informed me that about every ten days the bowels were not open for two days, but this coincided with the days upon which the patient had not been given the pituitary gland, which the mother buys herself; on four or five occasions she has not ordered it in time. It is interesting to note that immediately the pituitary is resumed the bowels open normally again. The whole appearance of the child has changed since she has had the pituitary treatment. She looks now a fine healthy girl, the lethargy has disappeared, and she is full of energy and mental activity, in marked contrast to her previous state.

I asked my colleague, Dr. H. E. Archer, to do a glucose tolerance test, which he did, as follows, on June 6th, 1924.

Blood-sugar at 2.25 P.M., 0·11 per cent. (50 g. of glucose given at 2.30 P.M.); ¼ hour after glucose, blood-sugar, 0·17 per cent.; ½ hour after, 0·19 per cent.; 1 hour after, 0·15 per cent.; 1½ hours after, 0·135 per cent.; 2 hours after, 0·105 per cent. The urine collected at end of two hours gave a very faint reducing reaction. In the first half hour the blood-sugar rose above the normal threshold and there was at that period presumably a slight excretion of sugar in the urine. The fall to normal was slightly delayed.

A further test will be carried out later on (1) while taking pituitary extract and (2) after being for four days without it, to compare results. Dr. Archer suggested that it might at first sight appear that one was dealing with a potential diabetic. The case will require close watching for a year or more and further tests will be necessary before it will be possible to determine this matter.

Cushny[1] states that intravenous injections of an aqueous extract of pituitary gland cause pronounced effects in certain organs, especially in those containing involuntary muscle. When injected intravenously the blood pressure rises slowly and remains elevated for some time. The rise in blood pressure is longer maintained, but is smaller and less abrupt, according to Cushny, than when it is produced by adrenalin. The heart is generally slowed. "The stomach and intestine are aroused to stronger contractions under pituitary extract and their tone is increased, the relaxation being much less complete." He quotes Dale in the statement that the uterus contracts more strongly and relaxes less completely after pituitary extract, which he thinks arises from a direct muscular effect after hypodermic injection of pituitary extract. The increased secretion of the mammary glands Cushny believes to be probably caused through the rapid expulsion of the milk by the contraction of the unstriated muscles of the gland. It is interesting to note that Cushny states that "the administration by the mouth of the dried gland or its extract is not attended with any obvious result."

In a recent case of adiposis dolorosa which I showed before the Royal Society of Medicine the chief symptoms had disappeared and the condition had been nearly cured, or at any rate distinctly alleviated, by the oral administration of pituitary whole gland. Encouraged by this I determined to try the same method of procedure in the present case, and it appears to have been quite successful. Apparently the case is similar to one of hypothyroidism in which small doses of thyroid gland given daily effect such wonderful improvement in the mental and physical condition of the patient. The sugar tolerance test in the meantime is just interesting in that it is not quite normal, and yet so far we have not attained the typical pituitary glucose tolerance curve which was obtained in the case of adiposis dolorosa.

It is obvious that it would not do to administer pituitary promiscuously to all cases of constipation, as it would only seem to be indicated where there is a natural atonic condition of the bowel due to lack of this endocrine. Still, there must be many sufferers of this type, and it would be of distinct interest to learn the experience of others in dealing with these cases.

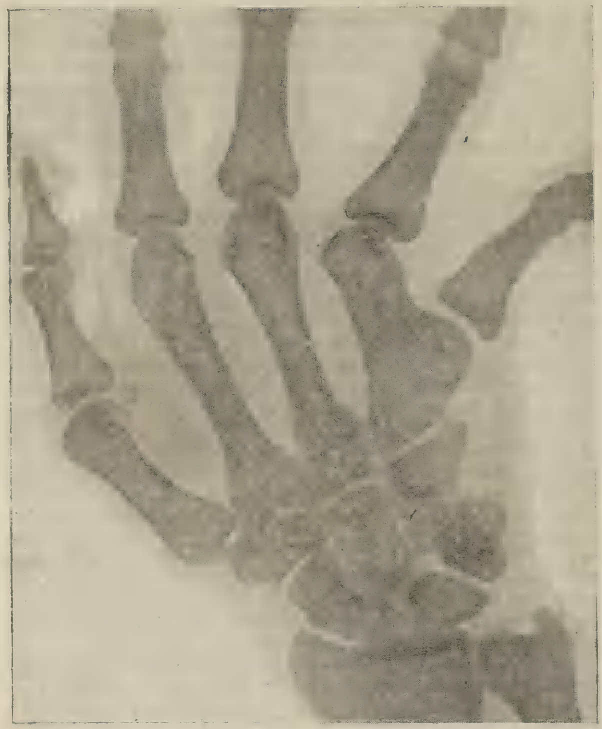
Clinical and Laboratory Notes.

CONGENITAL MALFORMATION OF HANDS.

By C. Marsh Beadnell, C.B., M.R.C.S. Eng.,
SURGEON REAR-ADMIRAL, R.N.

The following case of congenital malformation seems worthy of record.

The patient, aged 22, serving in the army, had been admitted for bronchial catarrh and hypertrophied tonsils. It was noticed that the hands were malformed. They presented in general outline the shovel-shaped "hands" of a mole; the digits, especially the fourth and fifth, were permanently deflected towards the hypothenar side. The grip was firm and no practical disability existed in consequence of the condition. There had been no traumatism. His father stated his son was born with the defect, and he thought a maternal uncle had a similar deformity. Wassermann reaction, taken on two occasions at an interval of a week, was positive. Denied acquired lues.



The following are the chief points differentiating the skeleton of the hand from the normal:—

1. The capitate bone fails to articulate with the fourth metacarpal.

2. The hamate bone of the left hand articulates on its distal hypothenar aspect with a small additional carpal bone. It was at first considered this was the pisiform which had been displaced from the triquetral bone to the hamate, but the radiologist (Surg.-Commander J. H. Rooney) is of the opinion that the pisiform is in situ proprio, and that the ossicle in question is a true additional carpal bone. It is not in evidence on the right side. The hamate also abnormally articulates with the third metacarpal.

3. The first and second metacarpals are in abnormal mutual articulation.

4. The fourth metacarpal shows considerable shortening, and is, apparently, fused throughout its length to the proportionally shortened fifth metacarpal. The common base of the two fused bones articulates with the hamate, and, on the left side, with the small ossicle mentioned above. The fourth metacarpal is prevented from articulating with the capitate bone by the abnormal junction effected between the hamate and third metacarpal.

5. The long axis of each of the phalanges, normally continuous with that of its metacarpal, is inclined towards the hypothenar aspect, that of the second and third digits being at an angle of 25°, of the fourth 45°, and that of the fifth being 80° to 90° to the normal. The first phalanx of the fifth finger articulates with what would appear to be the base of the fifth metacarpal.

Chatham.

A CURIOUS CASE OF PARTIAL UTERINE INVERSION.

By H. J. Drew Smythe, *M.C.*, M.B., M.S. Lond., F.R.C.S. Eng.,
ASSISTANT OBSTETRIC PHYSICIAN AND GYNÆCOLOGIST, BRISTOL GENERAL HOSPITAL.

Since chronic post-partum inversion of one half of a uterus didelphys must be a condition of extreme rarity, I am putting this case on record.

The patient, Mrs. G. S., aged 32, was sent to me as an emergency case by Dr. R. Britton, of Bristol, on account of recurrent attacks of severe hæmorrhage following her confinement.

The patient had had a left tuberculous hip since childhood for which she had had six operations, and it was now fixed and quiescent. Her obstetrical history was as follows. Married for nine years and had three previous pregnancies. At the first she had a stillborn child at eight months, at the second the child was born alive but developed paralysis, presumably due to difficult forceps, while her third was stillborn at full time. She states that she had chloroform and an operation for all of them in a hospital.

The present confinement took place on Feb. 10th of this year, when she was attended by a midwife and delivered of twins, one of whom died after three weeks. She remained in bed for 14 days. A week after the confinement uterine hæmorrhage commenced and was continuous up to her admission to the Bristol General Hospital three months later, at times being extremely severe.

Condition on Admission.—When admitted to hospital she was pale and collapsed and blood was trickling from the vagina at a fair rate. She was too ill on admission for operation or even examination and restorative measures were adopted. When slightly better I examined her and found in the vagina a large fleshy mass, which bled on manipulation, banging by a fairly thick pedicle from one side of the cervix which was patent for one finger. I made a provisional diagnosis of a cervical polypus, and the general condition having improved she was taken to the theatre and examined under an anæsthetic with a view to operating on whatever I might find. I then found that the body of the uterus was absent, and, to the right of the pelvis, a mass which I took to be an enlarged tube and ovary; in consequence I diagnosed chronic inversion.

Operation.—I attempted to reduce the inversion by pressure but was unable to do so, and in consequence I opened the abdomen with a view to incising the cervix at the internal os. I found a normally shaped uterus lying to the right of the pelvis having a tube and ovary attached to the right cornu, while the left side was smooth and completely covered with peritoneum. I could find no sign of the left tube or ovary and so presumed that they were inside the inverted half, neither was there any sign of an opening in the peritoneum at the side of the uterus through which the inversion had taken place. I immediately closed the abdomen and performed vaginal hysterectomy of the inverted half.

The patient made a complete recovery from the operation, but convalescence was prolonged by a left-sided pleural effusion of tuberculous origin; she returned home quite well some two months after the operation.

The interesting points about the case, besides its extreme rarity, are, first, that this abnormality was not discovered before, in spite of the fact that her three previous confinements were in a large hospital and necessitated instrumental delivery; secondly, her menstrual cycle was not fortnightly, as occurs in some of these cases; thirdly, that presumably in this confinement a fœtus developed in each half of the uterus; and lastly, that she did not die or at least experience profound shock when the acute inversion occurred at the confinement That it did occur then I do not think there is any doubt, as I was told by her friends after my operation that "something round and fleshy came out of the opening after the confinement and the nurse put it back."

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

THE opening meeting of this section was held on Oct. 11th, when Sir ARNOLD LAWSON delivered his presidential address on

TINTS AND THEIR VALUES.

He said the subject of tints had become a somewhat prominent one recently, and much had been written—reasonably and unreasonably—about the destructive effects of ultra-violet rays on human eyes. Owing largely to alarums for which the optical trade was responsible, the public seemed to have become largely imbued with a haunting fear of daylight, so that a large body of healthy people were wearing tinted glasses for protection. These glasses seemed to Sir Arnold Lawson to have been prescribed in an indiscriminate and indefinite way. Assuming the wave-theory of light to be correct, it was known that the visible spectrum extended from waves of light of 700 μμ at the red end to 400 μμ at the violet end. The infra-red rays could pass into the eye unimpeded, and the ultra-violet rays caused harmful chemical action. The eye possessed no direct protection from the luminous and infra-red rays, but Nature provided a good deal of protection against the ultra-violet rays. Experiment showed that this protection was furnished by the cornea and the crystalline lens, especially the lens; the cornea absorbed all waves of shorter length than about 290 μμ, while the lens was impervious to ultra-violet rays of shorter wave-length than 350 μμ. In the laboratory the ultra-violet radiation had been traced to waves of about 200 μμ, hence only a very small proportion of possible ultra-violet radiation could reach the retina normally. And ordinary sunlight at low altitudes was rather poor in ultra-violet rays; it contained few of shorter wave-length than 350 μμ. Also, protection from the heat radiation at the red end was to some extent afforded by the absorptive properties of the pigment lining the back of the iris and choroid, and by the pupil's power of contraction. In all human races the eye was self-adapted to endure without harm the sunlight of the particular part of the world they lived in. Hence healthy eyes, in ordinary circumstances, did not need protection by tints. The situation was, however, somewhat complicated by various subsidiary factors, the most important being (1) the intensity of the light, (2) the duration of the exposure, (3) the presence of glare, (4) occupation or trade. With regard to the first, extreme degrees of sunlight, especially in the rarefied atmosphere of mountains, were abnormally charged with ultra-violet and infra-red radiations, and this implied an increased dosage. The chief danger from the eye experiencing intense sunlight seemed to be from the red and not from the violet end of the spectrum. Concerning the duration of the exposure, under certain conditions of health, prolonged exposure to even moderate degrees of light might be harmful, due to a lowering of the natural resistance. As to glare, this might considerably complicate the patient's problem. Glare was the unpleasant effect caused by excessive reflection from below. Usually glare proceeded from snow, desert sand, rock, water, or chalk. The light, in glare, struck the eye in an unaccustomed manner, and it was something beyond normal experience. Snow reflected about 70 per cent. of the existing sunlight, and snow enabled the effects of intense light to be felt even when the direct sunlight was of but moderate intensity. The effects of glare were exerted rather in the luminous and infra-red regions of the spectrum than in the ultra-violet; hence it was reasonable to consider snow-blindness as due not so much to excess of ultra-violet radiation as to excess of exposure to the luminous and infra-red radiations. The conjunctivitis accompanying snow-blindness was probably due to sunburn of the conjunctiva. Dealing with the effects of occupation, he said that such trades as acetylene-welding exposed the worker to intense ultra-violet radiation; and, on the other hand, glass-blowers and workers in foundries were subjected to excessive heat-radiation.

Spectroscopic Values.

The President then passed to a consideration of the spectroscopic values of various tinted glasses. For this study, he selected London smoke No. 3, three shades of amber, five shades of Fieuzal, Crookes A, A2, B, B2, and peacock-blue. All the glasses so tested were of 2 mm. thickness, except that peacock-blue was examined in thicknesses of 0·5 and 2 mm. Thickness of glass was a most important point. The experiments were arranged by Mr. Hamblin, and the spectroscopic photographs he showed were executed by Dr. Judd Lewis, professor of physics at University College. These latter were embodied in a chart shown. With regard to ultra-violet radiation, the greatest absorptive power was noted from the darker Fieuzal tints, while the peacock-blue and the Crookes glass produced much the same effect. Next in order came amber shades, and the least protective was No. 3 shade of London smoke. All the Crookes shades had practically the same absorptive power, and none of the Crookes shades protected the eye against wave-lengths shorter than 350 μμ. The only tints which cut off all ultra-violet radiation were the darker shades of Fieuzal. For acetylene-welding the darker shades of Fieuzal were much better than Crookes glass, and in high altitudes and for snow-blindness nothing gave so much protection and comfort as Fieuzal 4 and 5 or peacock-blue. Concerning red and infra-red radiation, the peacock-blue was by far the most effective, especially when 2 mm. thick, next in order being Crookes B2 and Fieuzal 4 and 5. The various shades of amber were less effective than the corresponding shades of Fieuzal, and less so than a medium shade of London smoke or Crookes B2. All the various kinds of tint were equally effective in generally diminishing the luminous spectrum. Prescribers of tints should always pay special attention to the thickness of the tinted glass. Another series of photographs were taken showing the absorption of the tints when of only 0·5 mm. thickness. The absorption effect, in the case of the thin glass, was greatly lessened. A glass of less than 2 mm. thickness was likely to produce an effect considerably less than was expected. This consideration was of special value when ordering a tint without any incorporated lens, and when ordering a tint to be overlaid on a minus lens. In these circumstances it was well to specify the thickness of glass to be employed. It would be valuable if some scientific body, he said, such as this section, could agree on uniformity of glass thickness for prescriptions for these tints. No such uniformity existed at the present time. The President then passed to a consideration of the adaptation of these principles to the wearing of tints in health and disease.

Tints for Eyes Healthy and Aphakic.

Under ordinary circumstances, protection by ultra-violet glasses was quite unnecessary. When extraordinary circumstances were apt to be encountered, the two main factors to be considered were the luminous and the heat radiations, rather than the ultra-violet. In high sunlight and glare, the darker shades of Fieuzal were much more effective than Crookes glass, and for extreme cases peacock-blue was the most satisfactory. Artificial light was not stronger in ultra-violet radiation than was sunlight. Dr. Leonard Hill recently stated that in the case of an oil lamp, 97 per cent. of the energy was in the infra-red region, and of electric incandescent lamps, 95 per cent. Crookes A or A2 glass had the superiority that it afforded a general shade without materially disfiguring the appearance or altering colour values. There were many people with quite healthy eyes who were, however, physically or mentally abnormal. Often in physical disease and neurasthenia the general function of the eyes was impaired, and help was needed for them. Smoked glass was still as valuable as ever, but it was somewhat depressing, and Fieuzal did not so much interfere with the colour scheme and was as effective as smoked glass in other respects. The wearing of tints was apt to become a habit, and thus to lead to inability to endure bright light unaided.

With regard to wearing tints in disease and as a prophylactic against disease, it had been shown that cataract in glass-blowers was due to harmful infra-red radiation, not to the effect of ultra-violet rays. The best prophylactic tints were Fieuzal 4 or 5 and peacock-blue. In all cases of cataract tinted glasses should be worn in bright sunlight or glare. Glare by artificial light should be shunned as much as glare in sunlight. He often ordered two degrees of shade—one for moderate, the other for extreme degrees of light. After the extraction of cataract, the eye was deprived of its most powerful factor of protection against ultra-violet radiation. All aphakic patients should wear some protective tint out of doors, except on dark and cloudy days. In active inflammatory disease of retina and choroid he always ordered peacock-blue, which cut off all infra-red radiations, and most of the yellow and orange also. It had a very soothing effect on the patient.

Discussion.

Mr. **Harold Grimsdale**, in proposing a vote of thanks to the President for his address, thought a further use of tinted glass was to be found in the case of people towards middle life who manifested Pulfrick's phenomenon. That authority showed, by a series of experiments, that the perception of a stimulus varied with the intensity of the stimulus; therefore, if by any means the stimulus reaching one eye was weakened, as by putting tinted glass in front of it, the position of a moving object was falsely projected. Some people, for this reason, found a difficulty in exactly timing their strokes in sport. Sometimes after retro-bulbar neuritis, although the form perception had been recovered, the light perception had been somewhat reduced, and a moving object was seen in the wrong position.

Mr. **Ernest Clarke** referred to the early electric light with the carbon point, and the glare produced; and mentioned with satisfaction the present practice in many buildings of brightly illuminating a white ceiling, thus allowing the room to be served by a soft diffused light. A great point about Crookes glass was that it did not cut off luminous rays.

Mr. **Malcolm Hepburn** said he had found that the wearing of peacock-blue glasses on mountain climbing expeditions was not comfortable; the glasses had to be worn the whole time, whether one was climbing rock or snow, and differentiation was so difficult that a false step was easy. Green was preferable, in his experience, for these conditions.

Mr. **G. H. Pooley** (Sheffield) agreed that among the furnace-men the wearing of peacock-blue glasses seemed a source of great comfort, and certainly enabled the work to be done efficiently. In the North of England it was found that optical testers were ordering Crookes glasses in a wholesale fashion, with no such reasons as actuated the medical man, and the public felt that the extra price betokened outstanding merit. Healthy people with normally healthy eyes resorting to tinted glasses was a thing the profession should set themselves to discourage. He did not think it had been substantiated that infra-red rays caused any definite changes in the lens.

Mr. **Bernard Cridland** (Wolverhampton) said he understood from the manufacturers of Crookes glass that the tint had little to do with its optical properties, and that the tint was added because otherwise the public would not think the price was justifiable.

Mr. **Cyril Walker** (Bristol) referred to the success of smoky amber-coloured glasses in the case of a friend in Labrador; these enabled him to hunt and shoot without discomfort.

Mr. **Treacher Collins** also had a word of praise for amber-tinted glasses, following upon his own use of them. When people who came to him were likely to be exposed to ultra-violet rays he ordered them amber-coloured glasses. One such patient went to Tibet, and when he came back he said the rest of the party had snow-blindness, but he, having worn the glasses, was immune. He agreed that cooks and others exposed to heat derived relief from wearing peacock-blue glasses. He would like the President to extend his researches to pebbles.

Mr. **A. D. Griffith** thought the chief value of Crookes A lay in its absorption of the yellow band, by which the luminosity was reduced; this was the centre of the diffraction spectrum, and was the region of greatest luminosity.

Exhibition of Case.

Mr. **Rayner Batten** showed a patient with a peculiar appearance in the optic disc, which might be due to either a swelling or a depression. It was situated behind the scleral ring. Possibly it might be a clear-walled cyst.—The **President's** view was that it was a hole, with a vessel running across the bottom of it. There was a strong parallax.—Mr. **Treacher Collins** thought it might be a crater-like depression filled with neuroglial tissue, such as described by Coats.—Mr. **F. A. Juler** agreed with the President's view.

Dr. **A. F. MacCallan** read a paper giving his experiences in ophthalmic practice in Egypt, discussing the various operations, and his own procedure in the course of his work there.

SECTION OF PHARMACOLOGY AND THERAPEUTICS.

UNIVERSAL CURES, ANCIENT AND MODERN.

On Oct. 14th Prof. **A. J. Clark** delivered his presidential address, taking as his subject the consideration of some forms of quackery. Any general discussion of quackery, he said, was far too big a subject for a single paper, and therefore he would limit his remarks to certain universal cures, brought forward by men of considerable medical knowledge, who nevertheless appeared to have genuinely believed that they had discovered a universal cure for disease. Most of these cures appeared to have some real or supposed connexion with electrical phenomena. About 1750 the idea began to spread that the mysterious new phenomena of electricity and magnetism were manifestations of a force which, if properly applied, would act as a remedy for all known diseases.

Francis Anthony Mesmer.

This vague popular idea was first exploited on a large scale by Francis Anthony Mesmer (1733–1815). Mesmer started with an interest in astrology, and wrote his thesis for the M.D. of Vienna on the subject of the influence of the planets on the human body. He next spent many years experimenting with the Imperial Astronomer, Père Maximilian Hell, on the effects produced by magnets when applied to the diseased body, and he attained considerable success by practising in Vienna along these lines. He discovered, however, that he could influence patients without magnets and even without touching them, and thus developed a form of treatment by suggestion. Professional jealousy drove him from Vienna, and he went to Paris in 1778, where he attained sensational success by methods which really consisted in treatment by suggestion reinforced by an imposing display of imitation electrical apparatus. Mesmer enjoyed the support of a large and powerful section of Parisian society, but his methods soon found imitators and the wholesale exploitation of hysteria forced the Government into action, and a strong commission was appointed, including amongst its members Lavoisier and Franklin. After five months' inquiry the commission decided that Mesmer's apparatus was incapable of producing any electrical or magnetic effects. They admitted that patients were profoundly affected, but thought that more harm than good was likely to be produced and recommended the suppression of Mesmer's practices.

The most interesting points about Mesmer's success are as follows: he really did discover something—namely, the extraordinary effects that suggestion can produce in disease; on the other hand, he firmly convinced both himself and his patients that a complex and imposing apparatus, his famous tub, possessed marvellous powers of healing by the magnetic force it exerted, and yet the tub was incapable of producing the slightest electrical effect of any kind. The general similarity between Mesmer's tub and Abrams's oscilloclast is very striking.

James Graham.

In 1780 James Graham, who had studied medicine in Edinburgh and had picked up some knowledge of electricity in America, began to exploit electricity as a cure for all diseases. He converted a large house in the Adelphi in London into one of the most remarkable palaces of quackery that has ever been known. This Temple of Health was furnished throughout with most lavish ornateness—statues, armour, painting, mmense pillars and globes of glass, remarkably arranged plates of burnished steel, and electrical apparatus of every description were included in the decorations. The general effect was intensified by soft music from an invisible orchestra and perfumes of spices. The chief shrine of the temple was the Grand Apollo Apartment; this contained a throne, and above the throne a crown was suspended from which electric discharges could be produced. Patients were treated by being placed on the throne and having electric discharges played upon them. Graham was a tall, handsome man of commanding presence, and he reinforced the attractions of his electric sparks by providing a strong sex interest. He gave a ecture on the cure of sterility, with an entrance of six guineas, and in the words of a contemporary reported: "He uses the plainest language in dealing with the parts concerned with generation, yet ladies as well as men crowd to hear him without scruple." Graham issued his lecture in pamphlet form at the price of a guinea, and even by modern standards it must be ranked as remarkably obscene. In addition, Graham's temple contained the famous piece of apparatus, his "celestial bed." This was an ornate couch around which electric discharges could be produced. The bed was guaranteed as a cure for sterility, and couples were allowed to use it on payment of a fee of £50. There was, however, another side to his character, for he gave very sound hygienic advice to his patients, recommending cold baths and fresh air, ideas that were then extremely uncommon. In the later years of his life Graham became insane.

Elisha Perkins.

Prof. Clark considered the vogue of Perkins's tractors to be the most interesting example on record of the udden rise and fall of a universal delusion regarding a universal cure. For many years Perkins, who was the on of a doctor and a graduate of Yale, lived as a uccessful practitioner in Connecticut; he was a man of fine physique and remarkable for his untiring nergy. He was respected by his fellow practitioners, and acted as chairman of the local medical society. His strong personality and devotion to his professional duties won him a high prestige amongst his patients, and he was much impressed by the amount of benefit hat patients appeared to derive from his mere presence. Perkins concluded that his personal influence was due to some occult magnetic force, and made experiments in treatment by the application of magnets and metals to the diseased parts. In the year 1796 he invented his famous metallic tractors. These tractors were two sticks of metal, about as thick as lead pencils, one looking like brass and the other like steel. They were made of a mixture of various metals, including silver and gold, and were sold for five guineas a pair. Perkins believed that these tractors were capable of benefiting or curing practically all diseases both of men and animals. Their method of application was as simple as the tractors themselves, for it consisted in simply drawing the tractors downwards over the affected part for 20 minutes, and no previous knowledge was apparently needed for their application. Perkins demonstrated the use of the tractors in a number of hospitals, and his methods were endorsed by numerous doctors and professors, and he received the support of many of the leading men of the country such as governors and judges. In 1799 yellow fever ravaged New York, and Perkins went there to combat the epidemic with his tractors; he caught the disease and died after five days' illness at the age of 59. This ending proved conclusively Perkins's absolute sincerity. Yellow fever was not a disease which anyone would encounter with a remedy which they knew to be worthless, but one would have imagined that his death would have raised doubts concerning the efficacy of his tractors. The vogue of the tractors was, however, undiminished, and reached its height in England. In 1804 a Perkinean Institute was founded in London, with Lord Rivers as president. The institute enjoyed the support of 8 professors of four different universities, 21 physicians, 19 surgeons, and 30 clergymen. It is said to have had a larger endowment than any other hospital in London. There was, of course, opposition to the prevailing craze. In 1799 a Dr. Haygarth, of Bath, performed a few experiments with the help of some friends. They explained fully and impressively to a group of hospital patients that a miraculous new remedy had been discovered, and proceeded to treat them with imitation tractors made of wood. The results were striking; most of the patients declared themselves immediately cured or greatly benefited, although one or two stated that the pain of the treatment was so intense that they could not endure it. The hospital was soon surrounded by an excited mob demanding treatment with the new remedy. The experimenters apparently had a rather difficult and dangerous time when they had to explain that the whole business was a hoax.

Perkinism was a true artistic triumph in that a maximum effect was produced with the simplest possible technique. Half the civilised world was induced to believe that any disease could be cured by drawing over the diseased part two sticks of metal for 20 minutes. Twenty years later when the bubble had burst it still seemed incredible to one who remembered the craze that the whole thing should have been a complete delusion. The idea that an enormous effect can be produced without any rational cause is offensive to the ordinary beliefs of mankind, and with every craze one hears the identical argument that there must be something in it because it is so widely believed and supported. Perkinism was a remarkably clear-cut demonstration of the falsity of this assumption, and the whole history of the process shows how completely judgment can be inhibited by mass suggestion.

Albert Abrams, 1863–1924.

Dr. Albert Abrams was a medical graduate of Heidelberg, and practised for many years as an orthodox practitioner in San Francisco. About 15 years ago he began to seek for a universal cure for disease, and first brought forward the cult of spondylotherapy, which was a blend of osteopathy and chiropractic, with some of the more glaring absurdities toned down. Spondylotherapy, however, was dwarfed by Abrams's next step, his discovery of the famous electronic reactions.

The electronic reactions of Abrams are obtained by two machines, one a diagnostic machine and the other a curative machine, of which the diagnostic machine was the original and fundamental "discovery." An examination of Abrams's publications, the lecturer said, showed that his ideas developed step by step from some theories put forward in 1913 by an electrician who detected by delicate galvanometers the well-known skin currents, and thought that their measurement would provide a means of diagnosing and locating disease. This theory advanced by an electrician with no knowledge of medicine was developed by Abrams, who had some knowledge of medicine, but apparently no knowledge of electricity. This accounted for the final bizarre form of his theories. Naturally Abrams was able to get equally good results whatever modifications were introduced into his apparatus, and his followers have found the same.

Abrams soon passed from the diagnosis to the treatment of disease. Starting from the fundamental idea that disease is due to derangement of the vibration rates of the electrons, he sought a method of altering these rates, and devised his oscilloclast, a form of electrical interrupter. The oscilloclast was intended to pass into the body electronic energy of the same wave-length as the erring electrons in the diseased tissue. Abrams's theories violated all the known laws of physics and physiology even more completely than did the theories of Perkins. The great expense of the machines rapidly provided a strong commercial interest in support of the electronic methods, and public interest was sufficiently aroused for a leading popular scientific paper, the *Scientific American*, to offer to undertake an impartial investigation of the whole matter. This proposal was endorsed by the electronists in general and Abrams in particular. The committee of investigation found, however, that it was practically impossible to arrange even the simplest tests, and the investigation which they imagined would take a few weeks took nearly a year. The final report, just published, simply stated that as far as the committee could ascertain the so-called electronic reactions did not even exist.

The general argument of the electronists was that tests were superfluous since they could support the truth of their claims by innumerable testimonials from patients cured of every kind of disease, but unfortunately, the lecturer said, history failed to record any variety of quackery that had failed to obtain testimonials from persons who had genuinely believed themselves to have been benefited by its methods.

The lecturer concluded by saying that these universal cures simply represented the old quest for the Elixir of Life in a new form, and arose to satisfy the fundamental craving of the mass of humanity for a miraculous cure for disease.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

A meeting was held under the auspices of this Association in the rooms of the Medical Society of London on Oct. 8th, with Dr. L. R. Lemprière, the President, in the chair, when a discussion took place on

The Relative Values of Stone-milled and Other Flours and Breads, &c., in Relation to the Nutrition of the Growing Child.

Dr. Robert Hutchison opened the discussion by pointing out that the subject had given rise to much controversy which was still continuing. He himself could claim to be fairly impartial, as although after considerable study of the question some years ago he had concluded that the balance of scientific evidence lay in favour of white bread, recent evidence, including that relating to vitamins, had to some degree modified his opinion, and he now thought that on the whole the advantage lay with stone-ground bread. He was, however, uncertain how great that advantage was. Dr. Hutchison then explained the important differences in the chemical composition of the various layers of the wheat berry. The outer protective covering, known as bran, consisted of two layers—an outer coat consisting chiefly of mineral matter and cellulose, and an inner coat with some protein. The endosperm forming the great bulk of the berry was formed mainly of starch with some granules of protein (glutein) interspersed among the starch. The germ or young plant formed only 1½ per cent. of the whole berry and consisted of protein, fat, and mineral constituents (especially phosphorus), with only a little starch. The water-soluble vitamin present was contained mainly in the germ and parts of the bran, while the endosperm was almost free from vitamins.

Modern roller mills usually produced a white flour containing about 70 per cent. of the berry from the endosperm only. The old-fashioned stone-ground flour contained about 80 per cent. of the berry, and included all the endosperm, much of the germ, and inner layer of bran. Hence the stone-ground flour was richer in proteins, phosphorus, and vitamins than the roller mill flour. The difference in total protein content was certainly not very great, since the inclusion of the whole of the germ would only raise the protein content by 0·6 per cent. above that of white flour, and in some cases it even happened that a white flour made from the endosperm of a strong wheat contained more protein than a stone-ground flour from a weaker wheat. But it was now realised that the quantity of protein was not the sole question; the quality might be even more important, since different proteins varied greatly in biological value and tissue-building capacity. The proteins of the germ were now known to be peculiarly valuable biologically, and worth much more than those of the endosperm. The recognition of this was one of the great advances in the subject made in the last 20 years. Phosphorus was another constituent in which stone-ground flour was superior. While little was known about the exact combination of this, it was undoubtedly present in a form available for growth and of real value. Vitamins were the third important constituent in question, but Dr. Hutchison would not discuss these in detail since other speakers would refer to them. With regard to digestibility, there was no appreciable difference between stone-ground and white flours if the breads were well made. Experience in the war showed that, if finely ground, even wholemeal flours were absorbed far more completely than had been supposed.

Considering the bearing of these facts on the nutrition of children, the speaker pointed out that a child had three especial requirements. First, abundant energy value or calories, of which it had been calculated that for growth in weight of 2 kilos a year alone a consumption of 800 calories a day was necessary. Secondly, a high protein content compared with that needed by adult life, and of the proteins some must be of good biological value. Much mineral constituents, especially phosphorus and iron, were also necessary. Lastly, sufficient vitamins were essential. The extent to which these requirements were met by the two forms of bread was as follows. In energy value both forms were sufficient. In protein content the wholemeal or stone-ground flour showed a definite advantage owing to the high biological value of its proteins. It was true that in children fed on an abundant mixed diet the protein content of their bread was not of great importance, since proteins of high biological value were best obtained from animal foods. But in children whose diet consisted chiefly of bread with only a little milk or meat, this difference in proteins between the two breads might make the whole difference between a good diet and a bad one. Similarly with the mineral constituents an abundant mixed diet contained plenty of calcium salts in milk and of phosphorus in eggs, but a diet composed chiefly of bread might easily be deficient, especially in phosphorus. The question of vitamins Dr. Hutchison preferred to leave to other speakers, but he considered that any opinion as to the relative values of white and stone-ground flours must depend mainly on the importance attached to these substances. He personally thought their importance was exaggerated at the present time, although he agreed that vitamins were necessary for healthy growth, and that their absence could cause certain diseases as beri-beri or scurvy. In 25 years at the London Hospital he had only seen one case of beri-beri (from the East) and one of adult scurvy (as distinct from the quite different infantile scurvy), and he considered that if diets were so frequently deficient in vitamins as to cause much vague general ill-health there would be a larger number of cases that fell over the borderline into fully-developed scurvy or beri-beri. He concluded that if a diet was right in the other respects, such as calories and protein content, the vitamins could be left to look after themselves. The best course was to aim at an abundant mixed diet, and the proper solution of the problem was to make food cheap and abundant. Given that, the vitamin question and that of white or wholemeal flour was relatively unimportant.

Dr. C. E. SHELLY (Haileybury) continued the discussion by saying that most of those present would agree with the general statements of Dr. Hutchison. He himself wished to call attention to three important facts bearing on the question. First, the experience of British and coloured troops in Mesopotamia during the war, as related by Sir David Bruce in his presidential address at Toronto. This experience showed conclusively that troops whether white or coloured suffered from beri-beri when fed on white bread, but were practically free from it when fed on native bread. Secondly, former prison experience showed that criminals doing hard labour would keep healthy on a diet of (stone-ground) bread and water. But nowadays a diet of white bread and water would kill a man in three weeks. This had also been proved to hold for rats and guinea-pigs. Similar experiments at Copenhagen showed that hard-working men could keep healthy for six months on a diet of wholemeal bread and margarine, but if fed on white bread and margarine they could scarcely walk after two weeks. Thirdly, the rise and development of every great civilisation was coincident with the intensive cultivation of wheat by the peoples concerned. From these facts it must be inferred either that white roller mill flour has a deleterious constituent added to it or that it is lacking in some necessary constituent of diet. Dr. Shelly then described in detail the process of grinding in stone mills and roller mills. In stone mills the whole berry was ground up together, forming wholemeal flour. Since this flour was said not to keep well, and since the bran was said to have an irritating action, the flour was then sifted through sieves of fine silk mesh, which retained almost all the bran and only very little of the germ. The product was called millstone flour and contained over 96 per cent. of the germ. Further sifting with finer sieves could be used to produce finer and whiter flours containing smaller percentages of the whole berry. The advantages of millstone flour were that it was a complete food sufficient in itself to maintain life; it was a cheap food, as although its cost was slightly greater than that of roller mill flour, bread made from it went farther as people ate less of it, and lastly it encouraged mastication, and was therefore of great value to children. In roller mills the germ was cut off the grain at the beginning of grinding and the bran removed by sifting. The germ and bran were sold as offal for pigs and cattle, and the white flour, deficient in proteins, phosphorus, and vitamins, was sold for human beings, often after bleaching by chlorine or hydrogen peroxide. Finally Dr. Shelly related some interesting experiments on the radio-activity of various samples of flour and bread as tested by photographic plates. Photographs were shown illustrating these experiments. He then concluded by emphasising the danger and unfairness of forcing children to take bread which did not contain the nourishment to which they were entitled.

Miss MAY YATES (Hon. Secretary, Bread and Food Reform League) pointed out that the question at issue was the percentage of the whole berry to be retained in flour, and not the type of mill in which the flour was ground. If the demand were sufficient modern roller mills could and would produce wholemeal or 80 per cent. household flour instead of white flour. It was therefore unwise to emphasise the terms stone-ground or roller-milled, and better to describe flour as wholemeal or 80 per cent. or white.

Dr. O. G. WARD described the process of roller mill grinding, and agreed that these mills could produce flour exactly equivalent in percentages to stone-ground flour.

Mr. J. A. GARDNER (St. George's Hospital) described nutritional tests on various flours made during the war. These showed that in digestibility and availability there was little difference between 80 and 90 per cent. flour. Such difference as was found was slightly to the disadvantage of 90 per cent. flour, which caused an increase of 50 per cent. in the dry weight of the stools of patients over that obtained with bread from 80 per cent. flour. This was on a diet of which bread formed 50 per cent. of the whole. Tests of the health of munition workers eating bread made from various flours for two months showed that 90 per cent. flour certainly did no harm to men, women, or children, even when their diet consisted largely of bread; and a few of the workers showed great improvement in health owing to the cure of chronic diarrhœa or constipation. After the test was discontinued the workers sent up a demand for the continued use of 90 per cent. flour.

Sir HARRY BALDWIN said that from the dental point of view he agreed with previous speakers, except that he considered avitaminosis was responsible for a great deal of the general ill-health now prevalent. A striking fact was the deformity and poor development of jaws and teeth, which had become widespread among civilised people in very recent times. He considered this partly due to avitaminosis in early life, and suggested that the prevalence of adenoids might be due to the same cause. Dental caries, while partly due to defective development, was largely due to local adhesion of sticky carbohydrate food to the teeth and gums, and subsequent lactic fermentation. In this respect fine white bread was undoubtedly worse than stone-milled bread. He himself used only stone-ground and wholemeal flour, and considered it most important that people should not be deprived of valuable constituents of diet in order to pander to a vitiated taste.

Dr. G. E. FRIEND (Christ's Hospital) said that for the last 22 years the boys at Christ's Hospital School had been given stone-milled bread made from 76 to 80 per cent. flour. In the last two years some bread from 90 per cent. flour had been introduced. This was popular if taken occasionally, but was disliked if provided as the sole form of bread. Dental caries—as shown by annual inspection—had declined from an average of four teeth per boy per year before the stone-ground flour was used, to about 1·7 teeth per boy per year at the present time. While not suggesting that this improvement was entirely due to the change of bread, the speaker did consider 80 per cent. bread of great value for the teeth, especially because it ensured proper mastication. Further advantages of such bread were increased oral cleanliness from its roughness, and a reduced tendency to constipation. Dr. Friend finally emphasised the importance of pressing for improvement in quality of the bread for the people.

Mr. CARTER gave his experience as a baker, and explained that most people would not buy wholemeal loaves but demanded white bread. If there was a demand for wholemeal bread bakers would be quite ready to make it.

After some further discussion the PRESIDENT concluded by saying that the general opinion of the meeting appeared to be in favour of 80 per cent. stone-ground flour. He therefore proposed that the following resolution should be sent to the head-masters of public and private schools and to other educational authorities as representing the opinion of one section of professional thought :—

"That whiteness of flour is not in itself necessarily an indication of its value as a food, but that natural germ-containing bread made from 80 per cent. flour tastes better and is more nutritious, particularly for growing children, and should be provided."

This resolution was seconded by Sir BRUCE BRUCE-PORTER and was carried unanimously.

An attractive exhibit was shown by Messrs. Prewett, of the Town Mills, Horsham, of wholemeal and mill-stone flours, and of biscuits, cakes, pastry, and bread made from them.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.

POST-GRADUATE COURSE.

(*Concluded from p. 774.*)

IN addition to the lectures reported in our columns last week, the following were also delivered at the St. Mary's Hospital Post-Graduate Course held on Oct. 4th, 5th, and 6th.

Diet and Disease.

Prof. B. J. Collingwood said that our knowledge of diet rested on two foundations, laboratory experiment and clinical experience. So far as definitions were of value, a correct diet might be defined as one that maintained the normal composition of the blood and lymph. To attain this end there were five equilibria which must be satisfied in addition to the all-important question of vitamins. The water equilibrium : This was the most essential of all the equilibria. A sufficiency of water was the first necessity of diet, upon such sufficiency vital processes were dependent. A hunger strike might last for weeks ; a thirst strike would end in a few days. The calorie equilibrium : The maintenance of weight was evidence that this equilibrium was being maintained. The nitrogenous equilibrium : The clinical evidence of the maintenance of this equilibrium was the absence of muscular wasting. The mineral equilibrium : This equilibrium could look after itself except in cases where abnormal diet conditions prevailed, as, for instance, in certain parts of Africa where sodium chloride was almost unobtainable. The acid-alkali equilibrium : This could be upset towards the acid side by a diet extremely rich in fat, and very deficient in carbohydrates and proteins.

To understand the principles underlying diet in diseases of the alimentary canal, it was necessary to utilise our knowledge of the functions of the stomach, the small intestine, and the large intestine. The stomach absorbed no food, unless one were to class alcohol amongst foods, and since a large proportion of alcohol consumed was oxidised in the body, alcohol was, in that sense, most certainly a food and a source of energy. The small intestine was the only portion of the alimentary canal which absorbed food to an appreciable extent. The large intestine absorbed practically nothing beyond water. Nutrient enemata only nourished the bacteria of the intestine. Minute amounts of amino-fatty acids might, indeed, be absorbed. As to carbohydrates, if a diabetic on a diet just within the limits of carbohydrate tolerance were given an enema containing a large amount of dextrose, none of that substance appeared in the urine. Carbohydrate, if absorbed, was absorbed only in small traces. The lecturer said that the application of these facts to diseases of the alimentary tract was the foundation of correct dietary. If, for instance, the food for any reason—e.g., pyloric stricture—could not reach the small intestine, we must utilise saline enemata, remembering that these could maintain the all-important water equilibrium but none other. (In a discussion after the paper, the possibility of utilising intra-peritoneal injections of dextrose was suggested.) If, on the other hand, the large intestine was diseased—e.g., dysentery—the diet should be such as would leave no residue of undigested food to pass through the ileo-cæcal valve. In diseases of metabolism such as diabetes and gout, the objects of dietary were to maintain the above equilibria with a minimum of such articles of diet as was inimical to the morbid condition—i.e., carbohydrates in diabetes and nucleo-proteins in gout. The treatment of the albuminuria of pregnancy by a purely water diet was an example of the fact that the body suffered little if the water equilibrium were maintained, although the calorie and nitrogen equilibria went entirely to the wall.

Surgical Treatment of Gastric Ulcer.

Prof. C. A. Pannett said that he believed gastric ulcer was a comparatively rare disease, although there were always cases of it to be found in hospital. The essential treatment of gastric ulcer, he said, was initially always medical and never surgical, but under medical treatment there were a certain number of cases which would not get well. The pathologist looked on gastric ulcers as true digestive ulcers. In the evolution of the condition there was a time when there was loss of resistance to digestion. The chief factor in the prevention of healing was held to be infection, and secondly, the irritating nature of gastric juice which formed thick fibrous tissue round the ulcer. This fibrosis rendered all tissues in the neighbourhood of the ulcer rigid. The important question from the surgeon's point of view was which type of ulcer would heal and which would not, and here the X ray was of inestimable service. If a burrowing ulcer surrounded with fibrosis were present the X ray picture showed on the taking of a barium meal a niche at the site of the ulcer, usually on the lesser curvature, and opposite to that there was sometimes a spastic notch in the greater curvature. Some observers abroad stated that they could diagnose successfully more than 90 per cent. of cases by these means, but the figures at St. Mary's Hospital were rather between 70 and 80 per cent. The diagnosis of ulcer on the posterior wall of the stomach was a more difficult matter, but the fixation of the organ gave a clue when the patient was in the erect posture. Where there was a definite niche, unless it was of extremely small size, Prof. Pannett said, it was impossible for natural healing to take place, and operative treatment was called for. Where no niche could be discovered and yet pain was a regular and recurrent symptom, then he considered operation should also be advised, since every ulcer cannot be visualised by X rays. The general pathology of duodenal ulcers was very similar to that of gastric ulcers, but duodenal ulcers were more likely to be multiple, and they were usually of smaller size when they came into the surgeon's hand. They could, on the whole, be induced to heal more readily, perhaps because they gave symptoms earlier. It was much more difficult to come to a positive conclusion by X rays because of the position of the duodenum behind the stomach and also because the duodenum filled for a time then collapsed ; therefore exposure must be timed when the duodenum was actually filled. The indications for operation in duodenal ulcer were, when medical treatment proved ineffective, and secondly, where a definite niche was seen on the skiagram. The operation Prof. Pannett advised for ulcer high on the lesser curvature was a sleeve resection. This gave excellent results. Billroth I. was performed when the ulcer was nearer the pylorus, but there was a revulsion nowadays, he said, against gastro-jejunostomy. This latter operation, however, was useful when the ulcer had healed and formed an obstruction. The occurrence of failures, even after successful operations, should be explained, he said, by the patients losing antipeptic power.

The Diagnosis of Acute Right Hypochondriac Pain.

Mr. Zachary Cope said that the right hypochondrium was packed with important viscera, all of which moved slightly with the excursion of the diaphragm ; these viscera were so closely related together that if a sword with a blade 2 inches broad were thrust with precision through the centre of the region it would injure eight important structures—to wit, liver, gall-bladder, duodenum, pancreas, kidney, colon, the diaphragm, and the pleural cavity, not to mention the suprarenal. It was clear, therefore, that the problem of differentiation of the pains which took origin in this region was fraught with difficulty and was worthy of special attention. The first thing to be decided was whether the source of the pain was above or below the diaphragm. This was not always so easy as might appear at first sight. Both cardiac and pulmonary disease might give rise to acute pain in the right upper quadrant of the abdomen. With cardiac failure due to an anginal attack the liver might become acutely engorged and painful and vomiting sometimes occurred; such a condition might at first simulate an acute abdominal condition—even a perforated gastric ulcer. In differentiating the two conditions it was necessary to note the enlargement of the liver and of the right side of the heart, and to look carefully for venous pulsation in the neck. In both heart failure and perforated ulcer the pulse might be small and irregular at first, but in the abdominal condition the pulse generally became almost normal after the first shock of perforation was over. With diaphragmatic pleurisy and pleuro-pneumonia on the right side one might find an extremely close simulation of disease in the right hypochondrium—a simulation which must have at times baffled every practitioner of medicine and surgery. The lecturer then briefly explained how a distinction could always be made with certainty by contrasting the main symptoms. Of all the points of distinction he attached most importance to (1) the presence of fever at the beginning of a thoracic condition, (2) the previous history of indigestion or chill, and (3) the infrequency of vomiting in adult pleuritic conditions. There were some symptoms which were never due to thoracic disease—e.g., testicular pain, pain on moving the right psoas, and hyperæsthesia of the abdominal wall below the umbilicus. There was one symptom, not often present, which he had nearly always found due to thoracic disease—i.e., pain referred to the subclavicular fossa. Most of the symptoms, such as rigidity of the abdominal wall, increase of the respiration-rate, fine râles in the chest, absence of much air entry at the right base, could be found equally well in either group of cases, and in some cases it might be impossible by ordinary clinical examination to tell for sure whence the pain arose. In such cases it would not be justifiable to give a general anæsthetic and explore, but it was justifiable to give morphia and a local infiltration anæsthetic and make a small 1-inch incision into the right side of the abdomen. The presence of a serious condition might then be ascertained or excluded and the further treatment made plain.

Of the affections of the viscera in the right hypochondrium one must consider biliary colic, cholecystitis, perforated or leaking duodenal ulcer, and infection of the kidney. With *biliary colic* there was often some premonitory uneasiness before the acute pain started; the pain sometimes was felt right across the upper abdomen and usually went through to the right subscapular region. It was not felt on the top of the shoulder unless there were in addition some local peritonitis irritating the diaphragm. The abdominal wall was not usually rigid. With *cholecystitis*, which extended through to the peritoneal coat, there was local rigidity of the abdominal wall, tenderness on pressure, and sometimes pain in the right supraspinous fossa. Jaundice was exceptional and slight. Fever was present. With an *acutely perforated ulcer* of the duodenum there was not, as a rule, much difficulty in diagnosis; the history of acute indigestion, sudden onset of pain, collapse, and the local signs in the abdomen were usually clear. Pain in the right supraspinous fossa was common. With a leaking ulcer of the anterior wall only the history might enable to distinguish from cholecystitis. With a *leaking ulcer of the posterior wall* the difficulty in diagnosis might be very great. The proximity of the renal pelvis to the back of the duodenum caused renal symptoms and tenderness at the right erector-costal angle. In such cases it was easy to take the condition for an infection of the kidney. The history was the most important factor in determining, and the exact mode of onset was always to be ascertained. *Infection of the kidney* was often preceded by a rigor, and there was usually fever of 102° or 103° F. Tenderness at the right erector-costal angle was very definite, and there were usually urinary symptoms at the onset. Afterwards the ureter might become closed and a tender renal swelling develop. With a *perinephric abscess* the onset was less acute and was often preceded by the occurrence of boils or of a whitlow. Fever was not high—about 100°—and there were usually no urinary symptoms except tenderness at the erector-costal angle.

The Investigation of a Case of Puerperal Fever.

Mr. Aleck Bourne said that it was important to distinguish between fever of non-puerperal origin, local uterine infection, blood infection, and a local extra-uterine lesion such as a pelvic abscess. Considerable assistance might be obtained by noting the time of onset of pyrexia in relation to the delivery. Thus fever of the first four days was likely to be of uterine origin, with or without extension of infection into the blood-stream, while at a later date it was more likely to be due to a local lesion such as thrombophlebitis, cellulitis, or salpingitis. It should always be remembered, however, that a urinary or mammary infection might cause high temperatures at any stage of the puerperium. The exploration of the uterine cavity should only be carried out when it was possible to remove something, and the only thing that could be satisfactorily removed, or needed removal, was a placental fragment. Membrane and clot would disintegrate and come away spontaneously, but placenta certainly required digital removal in most cases. The diagnosis of whether placenta was retained, and therefore the indication for exploration of the uterus, was the occurrence of hæmorrhage during the puerperium, especially if it occurred in gushes, and was repeated. Mr. Bourne said that bacteriological examination of the urine was essential in all but the most obvious cases of infection elsewhere, as bacilluria was so frequently a cause of puerperal fever. A culture from the cervical canal and even from the blood was useful for purposes of prognosis, and for making a vaccine should it be desired to institute vaccine treatment. In all cases a complete examination of the patient should be made, including careful inspection of a perineal laceration.

Dr. J. B. McDougall took as his subject

Some Practical Points in the Diagnosis and Treatment of Pulmonary Tuberculosis.

The lecturer referred in some detail to the work of Pottenger, of America, and discussed the influence of parenchymatous changes in the lung tissue with special reference to the effects which these have on the skin, subcutaneous tissues, and muscles. He traced the path of the reflexes usually found and instanced the great value which these surface changes had in diagnosis of acute exacerbations of pulmonary disease and in the diagnosis of chronic lesions. Muscular spasm or tension was an invariable accompaniment of acute parenchymatous disease, and atrophy of the skin, subcutaneous tissue, and muscles was to be seen in the more chronic forms of chest disease. He pointed out that the pathological changes in the soft tissues were for the greater part based on reflex motor and trophic disturbances which are a result of acute and chronic changes within the lung, the most common cause being pulmonary tuberculosis. The lecturer then dealt with percussion, and pointed out the great difficulty physicians had in giving practical application to the terms "light weight" and "heavy" percussion. He considered the purely muscular aspect of the question and recommended that percussion be divided into three species. The first species included the percussion stroke in which the finger alone is used, extension and flexion occurring at the metacarpophalangeal joint; the second species was that in which the hand and finger may be moved together, but at different rates, and the third species that in which the forearm may be used along with the hand and finger, flexion and extension taking place at the elbow, wrist, and metacarpophalangeal joints. At all times it was best to begin with the first species and "feel" for resonance. If the first species failed to elicit resonance then the second species might be employed, but not till the first species had failed. It was only rarely necessary to use the third species. If the second or third species were used before the first then there was a grave danger that areas of impaired resonance would be overlooked, inasmuch as the louder notes produced by the heavier varieties would set in vibration healthy lung tissue adjacent to diseased patches. It required the lightest possible percussion stroke to determine small areas of tuberculous infiltration, and he strongly recommended that the first species of percussion be employed in every case until it had failed to produce resonance. The lecturer then quoted some observations which he had made on the total leucocyte count in cases of pulmonary tuberculosis, and expressed the opinion that consecutive white-cell counts gave frequently reliable information as to the presence of active disease. He considered the possible causes of the phenomenon of the "leucocyte swing," and thought that they might be produced by a process of negative chemiotaxis. There was no evidence that they were associated in any way with anaphylactic phenomena. In conclusion, the artificial pneumothorax apparatus of de Carle Woodcock was demonstrated, and its use in cases of partial or selective collapse was mentioned. The lecturer also detailed one or two cases in which he had been successful in treating cases of spontaneous pneumothorax by aspiration of gas under manometric observation, aiming always at keeping the intrathoracic pressure above that of the atmosphere.

Reviews and Notices of Books.

Chemistry of the Blood in Clinical Medicine.

By O. L. V. de Wesselow, M.B., F.R.C.P., Chemical Pathologist, and Physician to Outpatients to St. Thomas's Hospital. London: Ernest Benn, Ltd. 1924. Pp. 255. 15*s*.

In his preface Dr. de Wesselow announces his intention "to describe concisely those aspects of the subject which are of interest to the clinician," and in the twelve chapters contained in this book the attention of physicians and surgeons is directed especially to the clinical applications of blood analysis. The first chapter deals exclusively with the composition of normal blood; the next three, comprising about half the book, treat respectively the subjects of acidosis and alkalosis, the blood-sugar, and nephritis. Chapter V. is devoted to blood-findings in tetany, whilst the remainder contain accounts of rickets, gout, fats and lipoids, hydræmia and anhydræmia, anoxæmia, miscellanea, and, finally, methods.

In the chapter on normal blood, the constituents, such as urea, non-protein nitrogen, &c., are considered, and their normal concentration and significance in the blood are discussed. Although we agree with the author that highly technical discussions would be out of place in his book, we feel that he has rather neglected an opportunity here in not briefly describing the normal metabolism. This section gives rather a static conception of the blood constituents, whereas the true one must certainly be dynamic. Thus there is no account of the interrelations between the urea, amino-acid, ammonia, and non-protein nitrogen content of the blood, and the description of each constituent is isolated, whereas a brief account of metabolism would draw the subject together. It is doubtful if any reader who has not made a study of modern chemistry could follow the description of the meaning of pH; and the acid-base equilibrium of blood is rather sketchily described. Apart from the fact that the physiological conditions are dealt with in rather a hurried manner, the chapter devoted to acidosis and alkalosis, which consists mainly of a summary of the literature, is very good indeed. The author has described the clinical applications of blood analysis to these conditions in a very full and complete manner. In Chapter III. the explanations of the rise in blood-sugar content following the intake of glucose would not find favour with several authorities upon this problem. For instance, the work of P. J. Cammidge and of K. M. Hansen is not mentioned at all, nor is there any reference to that of certain American observers who used very large doses of glucose. The clinical importance of the blood-sugar content is admirably described, and many little known but important phenomena are given. Thus the author calls attention to the lowered leak-point in early diabetes mellitus, when it is quite common to find sugar in the urine with a normal blood-sugar content. This almost unknown fact is of the greatest importance when one considers the number of physicians using the sugar content of the urine as their only means of regulating insulin dosage. The fourth chapter, on nephritis, consists of a summary of those views for which St. Thomas's Hospital Medical School has become famous. This section deals very fully with the significance of nitrogen and salt retention in the blood, and is obviously written by one who has had wide experience in this type of work. Nearly two pages are allotted to Ambard's coefficient, which is condemned, while relatively few lines are devoted to Addis's ratio, though it is stated that such a procedure "is the only method by which a defect in the amount of renal tissue present could be detected." For details of this method the reader is referred to the original paper, but many would be glad to have them set out here. No mention of A. Epstein's work is to be found in this chapter. The final chapter on methods is a little disappointing, inasmuch as only for a very limited number of the constituents dealt with in the preceding chapters is the method of estimation described, and different techniques for each are given. The disadvantage lies in the fact that for blood urea 3 c.cm. of blood are used, for non-protein nitrogen 3 c.cm. of blood are precipitated with trichloracetic acid, for creatinin 5 c.cm. of blood are precipitated with picric acid, and so on. By the methods recommended, at least 20 c.cm. of blood would be required for the estimation of urea, non-protein nitrogen, sugar, creatinin, and chlorides. Moreover, the blood proteins have to be precipitated separately for each estimation. We would suggest that Folin's system of blood analysis is preferable, where one protein-free filtrate can be used for all the above estimations, which, with several additional constituents, such as amino-acid and nitrogen, can be performed on 6 to 10 c.cm. of blood.

The volume deserves a warm welcome, since it is the first to appear on this subject by an English author. That Dr. de Wesselow is one of the most competent of his countrymen to write such a book cannot be doubted, and as a clinical work its value is very great. An excellent series of references is given; in a future edition, which is sure to be called for, they might with advantage be numbered in the text.

Renal Disease.

Modern Methods in the Diagnosis and Treatment of Renal Disease. Second edition. By Hugh MacLean, M.D., D.Sc., Professor of Medicine and Director of Medical Unit, St. Thomas's Hospital. London: Constable and Co., Ltd. 1924. Pp. 110. 12*s*.

Since the first edition of this monograph is so well known it is unnecessary to enumerate its contents; the second edition differs only in detail from the first. Drawings representing the microscopic appearance of certain renal lesions have been included, and the chapter dealing with the value of blood analysis has been considerably expanded.

As before, the introductory chapter, dealing with the theories of renal secretion, is clearly written, and, it must frankly be said, far superior to that found in the majority of physiological text-books. It is one of the few brief and lucid accounts of this difficult subject in the English language. The succeeding chapters describe the symptoms and signs, investigation and treatment of renal diseases. Records of a series of typical cases are included with valuable comments. To one or two statements exception might be taken. Thus, the author says that the estimation of non-protein nitrogen "is a somewhat lengthy and difficult process, necessitating care and some technical skill if the results are to be depended upon," and that "quite as much information is to be derived from the much simpler process of estimating the urea present." But surely nothing could be simpler than the estimation of non-protein nitrogen by Folin's method, whilst many authorities hold that the non-protein nitrogen content is a safer criterion than the blood-urea. Again, on p. 64, Prof. MacLean, speaking of the diastase test, says, "It is easy to carry out and very helpful as a rule in conjunction with the urea test." On the next page but one, however, he adds, "Personally, I attach very little importance to this test." The importance of allowing for the acidity and salt concentration of the urine in the estimation of diastase has been emphasised by many workers; the technique here described takes no account of these complications.

One factor at least which must have contributed very largely to the success of the volume is that the purely clinical observations, such as blood pressure, have not been lost sight of. The well-balanced chemical and clinical opinions make the monograph of the utmost value to all concerned with nephritis.

1700 MILES IN OPEN BOATS.

By CECIL FOSTER, Master Mariner, Captain of the s.s. *Trevessa*. London: Martin Hopkinson and Co. 1924. Pp. 173. 10*s.* 6*d.*

MANY of us have seen at Wembley, in the Ceylon court, the battered ship's boat in which Captain Cecil Foster, without chart, compass, or chronometer, sailed 20 men of the sunk *Trevessa* 70 miles a day for 23 days from the middle of the Indian Ocean to the north end of Rodriguez Island, only six miles from north to south, a wonderful landfall. But even more marvellous was it that, on the passage, in spite of severely restricted rations, he only lost two out of his 20 men. The total ration expenditure was 50 lb. of biscuit, 100 tins of milk, and 8 gallons of water, from which the average daily expenditure seems to have been 1¾ oz. of biscuit (at 8 A.M.); ¼ tin of milk (issued as a cigarette-tin lid-full at 8, noon, and 4); and 2¾ oz. of water (at 2 P.M.). The other boat under the chief officer sailed 200 miles farther in three days more, and reached Mauritius. What risks, even in these days, insistently dog seamen! How quickly a dangerous situation may develop at sea! On Sunday, June 3rd, 1923, *Trevessa*, of 3000 tons and 10 knots, was lying-to in heavy weather; at 10.30 P.M. the outlook for next day seemed more hopeful, and the situation caused no anxiety. At midnight M. Scully, A.B., came up on the bridge and reported he could hear water washing about in the forehold under the forecastle. On deck nothing appeared to be wrong, but the captain and the chief engineer went down to the forecastle, and, laying their ears to the deck, heard, above the noise of the storm, water swishing about below them. The ship was sinking, like the *Titanic*, by the head on an even keel. At 1 A.M. the captain gave the order to abandon ship, and at 2.15, though in a gale, the two boats, by very fine seamanship, were got away safely, with every man in them and with extra water, biscuits, and milk. At 2.45 the ship sank by the head. Luckily for the crew, Captain Foster was not without special boat experience. Torpedoed twice in one day in the war, he had had to sail 320 miles in an open boat in the North Atlantic, and he was now to prove a regular foster-father to his men. On the first day he gave them a biscuit but no other ration, no water; they could that day do without. Also he got all food arranged so it could not be secretly pilfered. Their difficulty was water, but they had rain they could catch on nine of their 23 days, and their methods for catching it (illustrated in the book) were most ingenious. Very soon their mouths became dry and slimy. Often they could not eat the biscuits, but, after chewing them, could blow them out of their mouths as dust. The milk was their greatest support, and that is why, no doubt, the Board of Trade has arranged that, from July, 1925, all ships' boats shall always have in them, in addition to the 1 quart of water and 2 lb. of biscuit per man already ordered, 1 lb. of condensed milk for each person who might be carried in emergency. Their water ration was treasured to the last drop; indeed, had they not been able on two or three days to catch as much water as they wanted from rain, they could not have lasted out. Captain Foster also made them sniff seawater up their noses, not swallowing any, and keep their heads and necks wet, which relieved thirst a little, and he also made them rub their feet when they swelled. The crowding in the boat and the boat's constant rapid oscillation were persistent hardships.

A simple, direct record of hardships stoutly faced, this book will be read by many, and given to boys at Christmas, it will surely send some of them to sea, while all its readers will feel that Captain Foster, Chief Officer J. C. S. Smith, and their companions, well deserved the reception and honours given them on their arrival home. A story reflecting greater credit on the seamanship, knowledge of navigation, thoughtfulness for his crew, and power of command of the captain of a ship, and of good discipline and good humour in a crew in difficulties, has rarely been told; and never more modestly. It should be in every ship's library. The book is well printed, illustrated, and indexed.

PRACTICAL DENTAL HISTOLOGY AND BACTERIOLOGY.

By H. C. MALLESON, L.R.C.P., M.R.C.S., L.D.S., and A. BULLEID, L.R.C.P., M.R.C.S., L.D.S., Assistant Dental Surgeons, Guy's Hospital. London: John Bale, Sons and Danielsson, Ltd. 1924. Pp. 72. 7*s.* 6*d.*

THIS is an admirable and practical book which fills worthily a gap in dental literature. The instructions are clear and concise, and should prove very useful to the dental student. Dental histology is admittedly a difficult branch of general histology, and calls for skilled technique owing to the fact that so many preparations consist of hard and soft tissues together. It cannot be expected that the dental student can become in any degree proficient in histological technique. He must, as Mr. Norman Bennet states in his introduction, be dependent on others to a considerable extent, but it is desirable that he should be familiar with the special methods employed in dental histology were it only that here and there a student may become sufficiently interested to take up this work and carry on the great traditions of the dental histologists of the past. The section on dental bacteriology, for which Mr. Bulleid is responsible, presents a more difficult task than that on dental histology. In no sense can dental bacteriology be called a special branch of general bacteriology, and if this section is less satisfactory, the fault lies with the subject itself rather than the author. As a guide to a practical course of laboratory work it would prove useful, but, unfortunately, no such course is compulsory at present for the dental student. Yet even in the absence of such a course the student should learn some useful knowledge from the notes on practical dental bacteriology. The book is well illustrated and the price is moderate. A few blank pages on which the student could make notes of methods not mentioned here would prove a useful addition in succeeding editions.

DIGESTIVE DISORDERS.

The Treatment of the Common Disorders of Digestion. By JOHN L. KANTOR, Ph.D., M.D., Chief in Gastro-intestinal Diseases, Vanderbilt Clinic, Columbia University; Associate Gastro-enterologist and Associate Roentgenologist, Montefiore Hospital for Chronic Diseases, New York City. London: Henry Kimpton. 1924. Pp. 245. 24s.

THIS beautifully illustrated volume discusses in 15 chapters the treatment of various disorders of the alimentary tract; we say "various" because the scope of the work is general rather than particular, and it would be easy to enumerate a long series of conditions of relatively frequent occurrence, which are not mentioned. This is at once the strength and the weakness of the volume, for it stresses the management of many common disorders and perhaps tends to encourage hasty diagnosis which may prevent effectual treatment. Some of the author's views, particularly those which he gives on achylia gastrica, are not in accordance with accepted teaching, nor are they, we believe, sufficiently supported by facts to justify the departure. The real value of the book lies in the illustrations, which are well chosen and beautifully reproduced.

Essays and Addresses on Digestive and Nervous Diseases and on Addison's Anæmia and Asthma. By ARTHUR F. HURST, M.A., M.D. Oxf., F.R.C.P., Physician, Neurologist, and Director of Advanced Studies, Guy's Hospital. London: William Heinemann (Medical Books), Ltd. 1924. Pp. 306. 21s.

WE welcome this volume of collected essays by Dr. A. F. Hurst. Its contents have in many instances appeared in the pages of this and other medical journals, and the author in his preface states that his object in republishing these papers is to express his present views on subjects where the advance of knowledge makes final judgment impossible. The field covered is a wide one—asthma, Addisonian anæmia, diseases of the stomach, gall-bladder, and appendix, and the hysterical element in organic disease being the chief subjects. In every case Dr. Hurst treats his subject with lucid and original intelligence, and there is no surgeon or physician in the country who will not read this volume with profit and, we believe, with interest.

SOME GERMAN WORKS ON TUBERCULOSIS.

Diagnostik und Therapie der Lungen- und Kehlkopftuberkulose. By Dr. H. ULRICI, Aerztl. Direktor des Städt. Tuberkulosekrankenhauses, Waldhaus, Charlottenburg. Sommerfeld (Osthavelland). Berlin: Julius Springer. 1924. With 99 illustrations, some coloured. Pp. 263.

THIS beautifully illustrated work is well suited to readers anxious to learn the latest and most important advances in the diagnosis and treatment of tuberculosis of the lungs and larynx. As one illustration shows, a binocular instrument is now available which enables three persons to see the same laryngeal picture at once. Of the value of this device, both to the student and the patient, there can be no question. Other modern procedures, of which the author gives a full and illustrated account, are thoracoscopy with cauterisation of pleural adhesions, and the Fahraeus test—the rate of sedimentation of the erythrocytes. The chapter on the specific and non-specific treatment of tuberculosis with such substances as tuberculin and non-specific proteins is short; the author has felt constrained to mention such methods as those associated with the names of Ponndorf and Petruschky, but he takes his revenge by subjecting them to a blighting criticism. With regard to the classification of pulmonary tuberculosis, it is worth noting that German authors, like Dr. Ulrici, generally adhere to the Aschoff school, distinguishing from the point of view of diagnosis and prognosis between the "productive" and the "exudative" forms of the disease. Dr. Ulrici adds a third form, "cirrhotic" phthisis, which possesses certain clinical characteristics of distinctive importance. This classification differs considerably from the one in vogue in this country, where students are taught to distinguish between broncho-pneumonic, pneumonic, fibro-caseous, fibroid, and pleural types. Dr. Ulrici's book deserves popularity; it is not too elementary for the specialist, nor too erudite for the general practitioner.

Die Behandlung der Kindlichen Lungentuberkulose mit dem Künstlichen Lungen-Pneumothorax. By Dr. HELENE ELIASBERG and Dr. PHILLIPP CAHN. Berlin: S. Karger. 1924. Pp. 54.

THIS is a very instructive little monograph, dealing with the artificial pneumothorax treatment of 125 children whose ages ranged from 4 months to 14 years. It used to be thought risky to collapse part of one lung in a child, but the authors have induced a partial pneumothorax in some of their cases on both sides simultaneously. Their material is hardly suitable for estimating the value of this treatment because it has been considerably modified from time to time, and the class of case selected for it has also greatly changed. Thus, in the period 1914–16 this treatment was almost exclusively reserved for cases of pulmonary tuberculosis with cavities, and it was seldom that the pneumothorax was maintained for more than half a year. With increasing experience the authors have extended their indications for this treatment to many cases of "closed" hilus tuberculosis, and have maintained the collapse of the lung for two or three years or even longer. Their results have, of course, improved greatly in consequence of these changes, but it is doubtful if lung collapse treatment for closed hilus tuberculosis in childhood will ever be extensively adopted; the procedure savours too much of rushing to the aid of the victor, of giving aid where it is hardly needed. There were, however, as many as 50 sputum-positive cases in this series, and 13 of the patients are still alive. But only six of these 13 were rendered sputum-negative and free from cough and fever. Considering how bad the prognosis is for sputum-positive tuberculosis in childhood, a recovery-rate of 12 per cent. is not to be despised.

Die Klinik der Beginnenden Tuberkulose Erwachsener. Vol. II., *Der Formenkreis der Tuberkulose.* By Prof. WILHELM NEUMANN, Privatdozent an der Universität Wien. Vienna: Julius Springer. 1924. Pp. 265.

THIS is a work with neither a table of contents at the beginning nor an index of contents at the end; so the reader must needs plunge into the work itself before he can get a bird's-eye view of the whole. But he will be repaid for his plunge. There is, indeed, very little about the treatment of early tuberculosis in adults, and for this reason the book has a good chance of still being up to date a score of years hence, which is more than can be prophesied for most books on tuberculosis. Great care and much space are devoted to the classification of the numerous manifestations of infection with the tubercle bacillus, the basis of the classifications being rather pathological and anatomical than clinical. Useful hints are given with regard to the simulation of rheumatism, neurasthenia, and various other complaints by early tuberculosis, and with regard to neurasthenia, in particular, it would be well if the apostles of psycho-analysis and treatment by suggestion would bear in mind that the neurasthenic is often the product of a drawn battle between the tubercle bacillus and the human tissues. Undoubtedly, this is a book crammed with much useful information by one who has been able to draw on a carefully studied and well-digested material.

THE LANCET.

LONDON: SATURDAY, OCTOBER 18, 1924.

A HOSPITAL CLEARING HOUSE.

LAST April the Minister of Health requested the Voluntary Hospitals Commission to inquire into and to report upon the extent of the additional voluntary hospital accommodation required in England and Wales and the best means of providing and maintaining it. In his foreword to the Red Cross report[1] on voluntary hospitals, which we briefly noticed a week ago, Sir ARTHUR STANLEY suggests that this reference to the Hospitals Commission should be extended. He would like inquiry to be made into the general need of hospital accommodation, the special categories in which the need of further accommodation is felt, and the possibility of supplying that accommodation, in part at all events, by better coördination and coöperation. And in this demand for a wider inquiry Sir ARTHUR STANLEY has the support of the British Hospitals Association. Dr. F. N. KAY MENZIES, who wrote the Red Cross report, deprecates the slightly apologetic attitude which the voluntary hospital system has adopted during a recent time of financial stress, and claims that the immense volume of work for which the voluntary system makes itself responsible is carried out more efficiently and more economically than it could be by any other known method or system. But at the same time he is keenly aware of the urgent need for extension of hospital facilities in certain directions, and it is not the voluntary hospitals alone which are concerned. As he pointed out to the annual meeting of the Hospitals Association last summer, at least four-fifths of the treatment available for the sick in the London area is already provided for out of rates and taxes, and it is easy to understand, although none the less to be regretted, how faulty has been the coöperation between voluntary hospitals and the developing municipal services. When, in 1909, the Education Administrative Provisions Act resulted in the gradual introduction of a medical service into public elementary schools, the growth of this service was so rapid that in a short time the number of London school-children examined ran up to more than 250,000 per school year. It could have been foreseen that medical examination was bound to be followed by demand for treatment, when steps might have been taken to forestall the flooding of the out-patient departments of voluntary hospitals with school-children suffering from various ailments to a degree which was little short of a public scandal.

The school medical service was, however, only the forerunner of a series of other medical services to be undertaken by local authorities, and now quite apart from the fever hospitals and mental hospitals the municipality of London has undertaken to deal with tuberculosis in 2400 beds and 33 dispensaries, with venereal diseases in 28 clinics, with maternity and child welfare at 220 centres, and to remunerate medical practitioners called in under the Midwives Act. These services are certain to expand still further in certain directions, such as the safeguarding of maternity, the care of infantile paralysis, and of the various manifestations of rheumatism in children. And it will need the collaboration of all the hospital authorities of the country to ensure that the expansion is well and truly engineered. It would be entirely unfair for the Hospitals Commission to find that such and such a voluntary hospital is failing to do its duty to the sick in any area until it has been definitely established whether the public authorities in that area are doing their duty to those for whom they are legally responsible. This cannot be determined without a comprehensive survey of existing facilities for the treatment of the sick, whether in voluntary or public institutions. Careful inquiry is needed in each county area as to the extent of all the facilities available for the treatment of the sick and the extent to which they are utilised. Dr. MENZIES outlines the scope of such a survey thus:—

> 1. Each county area will have to be carefully investigated in order to ascertain not only the exact amount of institutional accommodation for the sick (Voluntary, Poor Law and Public Health), but also all other facilities for diagnosis and treatment such as Dispensaries, Maternity and Child Welfare Centres, Clinics, &c.
>
> 2. Having ascertained this information, then it will be necessary to classify it into the various categories—Surgical, Medical, Special Departments, Mental, Fever, Chronic Diseases, &c.
>
> 3. The next step would be to ascertain from Medical Officers of Health, Medical Practitioners, Clergy and Ministry, and Social Welfare workers, as well, of course, as the Hospitals themselves, in what respects their experience proves there is a real deficiency.
>
> 4. Then, with a full and complete knowledge of the facilities available and the deficiences found by experience, it would be wise to consider how far known needs could be met by re-arrangement of existing facilities—how far additional Auxiliary Hospitals, Recovery Homes, and Convalescent Homes could meet the need by relieving the larger and more expensive Hospitals of cases now dealt with—how far Public Health Authorities could relieve Voluntary Hospitals of cases of Tuberculosis, &c.
>
> 5. Lastly, how far, after such re-arrangement, a real need existed for additional Hospital accommodation, whether Voluntary, Poor Law, or Public Health. It would not necessarily mean any additional Voluntary Hospital accommodation in every area.

This would mean a searching survey, but only after it has been made shall we know what gaps are left unfilled by either voluntary or public authorities. The need for a central bureau of hospital information becomes more apparent every year. Such a bureau should be available both for voluntary and public hospitals, and if properly run it would prove a trustworthy source of information on the countless difficulties which arise in hospital administration. A hospital committee may need information on technical points of architecture and engineering, on the supply and preparation of drugs, on the methods and success of contributory schemes, down to the comparative cost of various methods of cooking and the best process of laundering, and so forth. Any hospital secretary who wants information on any of these points at the present moment has to set about it in a laborious and cumbersome fashion by writing to some other hospital of which he chances to know the secretary or a member of the committee. It seems tragic that the vast practical experience of hundreds of hospitals should not be concentrated and tabulated at some central spot where it would be easily accessible and in charge of skilled administrators. The hospital world owes a deep debt of gratitude to the late Sir NAPIER BURNETT, who made the first survey for the Red Cross of the extra-London hospitals. Dr. MENZIES brings to the same task an intimate knowledge of municipal work, and we trust that the hospitals will avail themselves to the full of his administrative ability.

PHARMACEUTICAL EDUCATION.

THE opening of the eighty-third session of the School of Pharmacy comes as a reminder of the special place this venerable institution occupies in our educational scheme. In our time the founding of a new school is no uncommon thing, but in estimating the credit due to the founders of the School of Pharmacy we must consider the surroundings in which they lived and picture ourselves breathing the atmosphere which they breathed. In those days technical schools were unknown, and popular education was little more than a reformer's ideal. It required, therefore, both imagination and foresight to contemplate a school for specialised teaching and no small amount of courage to establish it. Thus it is seen that the founders of the school were men whose memories should be held in respect; whose proper ambitions should be handed down from one generation of students to another, as a basic tradition upon which to build from time to time other traditions equally inspiring. The founders were far-sighted pioneers; they saw, long before the leaders in many another class, that the day would come when the multiplication of the sources of knowledge would make it impossible for one man to become a universal genius or even supreme in one whole art; when specialisation would be essential to class or even personal distinction. In his address at the opening of the session, Mr. F. PILKINGTON SARGEANT, President of the Pharmaceutical Society, reminded the students that the need of such a school was one of the main reasons for the formation of the Society. It was seen by those who founded it that the most effectual method which any class of men could adopt for advancing their professional standing consisted in "a steady and persevering attention to intellectual improvement." Upon a groundwork of general knowledge, in assembling which the student learns the most important of all arts—the art of learning—they recognised that there must be erected a special structure of knowledge of those subjects which are allied to the practice of pharmacy. The Society was formed in 1841, and within a few months the school was opened and four men whose names are still familiar to students of botany, materia medica, chemistry, and pharmacy were appointed as professors. The laboratories which were equipped in the school 80 years ago were adopted as a pattern from which the Birkbeck laboratory was afterwards fitted up in University College; and the mantle of PEREIRA has fallen on a brilliant succession of teachers. It would be a lamentable thing if ever the Society, in search of economies, should make a beginning in its educational expenditure. We do not underestimate the value of organisation, but education is necessary if the organiser is to get material worthy of his scheme. As a mere trade union the Pharmaceutical Society could never have attained its present standing, which is in fact a direct consequence of its recognition of the value of education. Now, Mr. SARGEANT, quoting from the second Philippic, "Cui bono fuerit?" gave this answer from HERBERT SPENCER: "To prepare us for *complete* living is the function which education has to discharge." That, indeed, is the function of education, but when one looks at the windows and show-cases of the modern chemist's shop one is not inspired to quote either CICERO or HERBERT SPENCER. On the contrary, we believe there is a considerable section of pharmacists who ask who stands to gain and almost despair of an answer; who understand by specialisation the probing of one corner of the vast field of knowledge rather than the merchanting of toilet specialities. It is to these men that pharmacy looks for something more distinctive in the way of an outward sign of latent capabilities; in short, for a divorce of pharmacy proper from the thousand and one gew-gaws of which DIOGENES hath no need. Specialisation in production is not sufficient; there must be specialisation in practice, and we understand that a silent reformation is going on which in due time will result in two distinct kinds of practitioners, one of which will be the proper hand-maid of medicine. There can be no doubt which of the two types will be most welcome to the medical profession.

◆

THE PSYCHOPATHOLOGY OF ACCIDENTS.

AT the Conference of Industrial Welfare Workers, reported in THE LANCET of Oct. 4th, a discussion on the psychological and physiological aspects of accident prevention brought forward the suggestion that the state of mind of the person to whom or through whom an accident happened should be a matter for investigation. Dr. MILLAIS CULPIN, who opened the discussion, described several cases in which a pathological mental state, of the nature of a psychoneurosis, seemed to be a determining factor in the production of what had seemed to be straightforward "accidents." In these cases the people concerned were under treatment when the factors underlying the accidents—which had all happened long before—chanced to come to light. Mention was also made of a recent instance in which psychopathological factors were admittedly present and formed the subject of official investigation. On Feb. 23rd last, through the default of a signalman, a head-on collision took place near Stoke Works Junction on the London Midland and Scottish Railway between an express passenger train and a freight train. An inquiry into the accident was conducted for the Ministry of Transport by Lieut.-Colonel A. H. L. MOUNT, who paid special attention to the psychological aspects of the events which led up to it. From a report of this inquiry, which appeared in the *Manchester Guardian* of Sept. 20th, it appears that there had been handed to the signalman, when he went on duty on the night of the accident, a form charging him with insubordination and conduct unfitting him to be a signalman, and the man declared that this was the cause of the accident, inasmuch as it weighed so seriously on his mind that it had rendered him unfit for duty. Full consideration was given to this plea and the report, though deciding that the signalman could not avoid responsibility, chiefly on the ground that his deliberate decision not to ask for relief indicated an unjustifiable disregard for public safety, yet points out the error of judgment involved in handing the charge form to him when going on duty, and expresses the opinion that the human aspect of the case was overlooked in favour of the machinery of administration. Thanks to the careful and complete statement of the findings at the inquiry, the psychopathologist is able to read between the lines and at least feel that he might offer explanations of some doubtful points. The man, for example, claimed to have "mechanically" carried on his duties for an hour before the accident and to be unable to account for his actions during that period. As far as his recollection went he had been assisted by someone during that time, and for this false idea there is offered a theory of "truthful imagination" or the alternative of pure invention. To one familiar with states of dissociation it seems possible to place the incident in the category of fugue phenomena, and to that extent aid in the understanding of it. Such an explanation might make no difference in the final judgment, so far as the fixing of responsibility is concerned, but expert investigation of the most important element in the accident—the mental state of the agent—might have added greatly to the value and utility of the inquiry. A further development is invited by the description of the signalman as "a man of peculiar disposition and somewhat abnormal temperament," and by references which indicated that, like so many psychoneurotics, he was labouring under a sense of past and present injustice. It may be taken for granted that his physical fitness had been determined by careful examination, that his eyesight was adequate, that his heart and lungs were sound, and that he possessed no bodily defect that might become a source of danger in his work. But we have not yet reached the stage of making a psychological examination of a man's fitness for undertaking responsibility for the safety of other people. Indeed, we must confess that a medical man called upon to make such an examination might find very little in his professional training to help him in the task, and would have to fall back upon the nonexpert qualities of commonsense or intuition. Other difficulties come to mind, and objections to such an examination on the part of the workers might be not the least of them. One thing certain is that the case which prompted these reflections shows clearly the need for the study of the psychological aspect of accidents; if this obvious need were met the results might be expected to teach us something valuable about prevention.

◆

A GREAT MEDICAL EDITOR.

IN 1870 an English lad of 18, born at Moreton-in-the-Marsh, Gloucestershire, crossed to America and entered the University of Nebraska, where he won an important prize for an essay on the sheep industry. The lad was George Henry Simmons, who has just retired after 25 years' devoted service as editor of the *Journal of the American Medical Association*. On the occasion of the annual meeting of this Association in June last he was entertained to a banquet and presented with his portrait, but with characteristic diffidence he omitted to publish an account of the proceedings in the *Journal*, so that it is only now after the speeches and testimonials have been printed and privately circulated that we are able to give some account of the life and work of this great medical editor. After a brilliant career as a student at the University of Nebraska, Dr. Simmons began to study medicine and obtained a degree from a homœopathic school, after which he revisited Europe and obtained the midwifery licence at the Rotunda Hospital, Dublin. Not satisfied with this and while engaged in a busy practice he managed to obtain a supplementary degree from Rush Medical College, Chicago, and settling in Lincoln, Nebraska, he became a much-honoured member of the community. He founded the *Western Medical Review*, and in 1899 was appointed secretary of the American Medical Association and editor of its *Journal*. Although the Association had been established since 1847 and the *Journal* had been in existence since 1882 neither was in a flourishing condition, but from the moment Dr. Simmons took charge this state of affairs was changed and success attended his efforts from the first. From a circulation of 8000 the *Journal* increased the circle of its readers until now nearly 90,000 copies are printed each week, and this publication forms the chief source of income of the Association. But material success has not been the only result of the administrative abilities of George H. Simmons. The *Journal* has been conspicuous for its efforts to raise the standard of medical education in America, to cut down the number of inferior medical schools where the curriculum was inadequate to equip students as efficient practitioners of medicine, and in its campaign against quackery and all forms of medical fraud it has gained the support and admiration of the best elements of the medical profession everywhere. In connexion with this last Dr. Simmons was made the object of unprincipled attacks by the opponents of medical progress and by those whose means of livelihood had been impaired by the exposure of their frauds. The decision of the courts against the maliciously minded people who had thus attacked him was applauded by the whole community, and he has continued his efforts to teach the public what and whom to avoid both by the section on Propaganda for Reform in the *Journal*, which, week by week, deals devastatingly with some quack remedy or some patent-medicine vendor, and by the paper *Hygeia* which reaches a large lay public and endeavours to counteract the influence of the pseudo-medical columns in the less reputable newspapers. Nearly 500 of the leading members of the profession were gathered at the testimonial banquet to do honour to the man who, in the words of Dr. W. J. Mayo, has been "the greatest factor in the educational progress of the American medical profession in this generation." Prof. Harvey Cushing referred to him as an example of what America can do for an Englishman if it catches him young enough, and described him as "a man with energy, with vision and with administrative ability, willing himself to give untiring attention to details." In his reply Dr. Simmons modestly pleaded certain "extenuating circumstances," pointing out that the *Journal* had merely reflected the progress in medicine and medical organisation which had taken place during the last 25 years. At the age of 72 Dr. Simmons is now retiring from active work at his own request to enjoy the leisure which he so well deserves.

◆

MEDICAL CANDIDATES FOR PARLIAMENT.

NOMINATIONS of candidates for the new House of Commons will only be completed to-day, Saturday. The list of medical men who were returned to the House of Commons in December, 1923, was as follows:—

Members.	*Constituency.*	*Party.*
Sir George Berry	Scottish Universities	C.
Dr. W. A. Chapple	Dumfries	L.
Dr. F. E. Fremantle	Hertford, St. Albans	C.
Dr. L. Haden Guest	Southwark, North	Lab.
Mr. Somerville Hastings	Reading	Lab.
Sir Sydney Russell-Wells	London University	C.
Prof. T. Sinclair	Queen's University, Belfast	C.
Dr. E. G. Spero	Stoke Newington	L.
Dr. J. H. Williams	Carmarthen, Llanelly	Lab.
Lieut.-Col. T. S. Beauchamp Williams.	Lambeth, Kennington	Lab.

C., Conservative; L., Liberal; Lab., Labour.

Dr. Walter Elliot was returned for Kelvingrove, Glasgow, at a by-election during the session, and the London University seat became vacant through the death of Sir Sydney Russell-Wells on July 14th. We understand that with one possible exception all the ten sitting medical members are standing again for their party and constituency. Sir Richard Luce is standing in the Conservative interest at Derby, and Dr. Thomas Watts (C.) will fight again for the seat he lost at Manchester, Withington. Both of these, as well as Dr. Elliot, Dr. Fremantle and Dr. Spero, will receive the support of the British Medical Association. Dr. Brackenbury, we fear, is not able to stand at this election. A number of medical candidates with some previous experience of contests are again seeking the suffrage. In London, Dr. Addison is standing as Labour candidate for Hammersmith South, Dr. Alfred Salter for West Bermondsey, Dr. Ethel Bentham for East Islington, Dr. H. B. Morgan for North-West Camberwell, and Dr. Stella Churchill is contesting North Hackney. Other probable nominations are Dr. O. Gleeson (Lab.) for Portsmouth, North; Dr. J. J. Lynch (Ind. Lab.) for Walsall; Dr. I. H. MacIver (Lab.) for co. Argyll; and Dr. Laura Sandeman (C.) for Aberdeen. Although the total representation last session was not large, it was evenly distributed over the three political parties; we may hope that the numbers may be further increased by the return of other medical men and women willing to put their experience at the disposal of the legislative body at a time when it is specially needed. Polling takes place on Oct. 29th.

FACTORY AND WORKSHOP (NOTIFICATION OF DISEASES) ORDER, 1924.—Under this Order, which comes into force on Jan. 1st, 1925, the provisions of Section 73 of the Factory and Workshop Act, 1901, are to apply to all cases of (1) poisoning by carbon bisulphide, (2) poisoning by anilin and its compounds, and (3) chronic benzene poisoning occurring in a factory or workshop.

Annotations.

"Ne quid nimis."

THE SCOTTISH BOARD OF CONTROL.

THE principal facts of general interest in the latest report[1] are contained in the preliminary observations. It appears, in the first place, that there has been a moderate increase in the numbers of all types of patients under care—i.e., certified insane, voluntary boarders, and mental defectives. The Board have therefore considered, in general terms, the steps whereby additional accommodation can best be made available, and the policy which has emerged is not without interest. Against the obvious remedy of enlarging existing asylums is set this fact: "Experience has shown that large institutions, while more economically managed from an administrative point of view, are less efficient from that of the interests and welfare of the patients." When, therefore, a proposal is received for the extension of an asylum with already more than 700 inmates, the local authorities are asked to consider how far the situation can be met by any of three courses—the establishment or extension of observation wards, the boarding-out of quiet and harmless cases, and the provision of separate accommodation for mental defectives. The two former propositions are self-explanatory, but the last involves the whole policy of the Government in dealing with mental deficiency, a problem which, as indicated in last year's report, is still awaiting satisfactory and adequate solution. Mental defectives are still being sent to asylums, and it is pointed out that their condition is one totally distinct from acquired insanity, and requiring altogether different treatment. In the great majority of cases special education, which is only available in the institutions solely devoted to this work, is capable of rendering the individual fit for ordinary life under suitable private care and able to follow some useful occupation. The extent of the accommodation in such institutions will have to be greatly increased if mental deficiency is to be dealt with adequately in Scotland, and this will have the incidental effect of relieving congestion in the asylums. There is another class of patient for whom asylum treatment is perhaps unsuitable and certainly often unnecessary—the senile dement. According to this report, 20 per cent. of total admissions are cases "labouring under the mental states incidental to old age," and it is suggested that many of these might be accommodated in "cottage hospitals and homes rather than the elaborate and expensive institutions such as modern asylums are." A good deal of attention is being devoted to the provision of observation wards, which now exist at five important centres, and it is recorded that these "undoubtedly subserve the needs of many patients suffering from early unconfirmed or temporary functional nervous diseases and mental disorders." Another step in the same direction has been taken by certain parishes in Argyllshire and elsewhere, in paying for the admission of voluntary inmates to district asylums. This is so far being done only on a small scale, and part of the reluctance to institute such provision more generally is, of course, due to the fact that such patients are not taken into account in the lunacy grant, the cost of their maintenance being borne entirely by the local authority. That the Board look forward to much more elaborate and more general provision in the future for the needs of voluntary patients is evident. "In the treatment of all such cases," the report runs, "the Board have come to the conclusion that district boards, either individually or in combination, and the authorities of Royal asylums, should be empowered to establish nursing homes, hospitals, outdoor and indoor clinics, particularly by arrangement with the managers of general hospitals throughout the country, where anyone desiring advice, care, and treatment may receive it as a voluntary patient."

POLARIMETRIC ESTIMATION OF SUGAR IN URINE.

THE advent of insulin has made accurate urine-sugar estimation a necessity for everyone dealing with diabetes. Practically all the volumetric methods are difficult, and require great practice if consistent results are to be obtained. Moreover, they are unsuitable for general practice owing to the time required, the expense of solutions, and the tedium of washing up of apparatus used. In view of these facts, it is surprising that the hand polarimeter is not more extensively used by practitioners. These instruments, made by Zeiss and Reichert, and costing only a few pounds, are constructed to work with daylight, and have the length of their tube so adjusted that the scale reads off in percentages of sugar. On focusing the eye-piece, a circular field, divided diametrically, can be seen. If the tube is empty, and the scale set at zero, the whole of the field is of a uniform mauve tint. If, however, an observation tube containing diabetic urine is put into the apparatus the colours change, and the two sides of the field become uneven in tint. The scale is turned until the colours match, and the percentage of glucose can be read off directly on the scale. If the urine is very deeply coloured, 40 c.cm. should be shaken up with 10 c.cm. of 20 per cent. basic lead acetate solution (which is opalescent) and filtered. Observations are then taken on the clear fluid, but one quarter of the percentage read off must be added to allow for dilution. The only theoretical objection to this method is that lævo-rotatory substances such as β-oxybutyric acid may be present thus tending to lower the glucose rotation. This hardly comes within the sphere of practical politics, owing to the small quantities of these bodies present and to their low specific rotation index. In any case this error is preferable to those made by anyone not in constant practice who performs volumetric analysis. This method described is used as a routine in certain of our great hospitals and much valuable time is saved.

MICROSCOPIC ILLUMINATION.

Mr. Conrad Beck's treatise on the microscope,[1] written as it is by one who makes them, is calculated to be of great practical value to all who use microscopes. One chapter is frankly devoted to products of the writer's factory; the rest of the book might have issued from some purely academic source. In writing on aperture, photometry, glare, and illumination, Mr. Beck has, in places, broken new ground and his whole treatment of them is marked by unusual discernment. The accepted rule as to the relation between aperture and resolution is perhaps stated too positively. The limit of resolving power for ruled lines which has received the imprimatur of the Royal Microscopical Society is very useful to the students of Grayson rulings, but it is almost without significance in relation to such objects as bacteria which take the form of dark (or coloured) lines or dots irregularly placed on a bright field. Lord Rayleigh showed that a single dark line under these conditions would be a visible object even although its actual width should fall considerably short of the half wave-length of light. The remark applies with even more force to a small circular or approximately circular object, and it is a serious shortcoming in books upon the microscope that this problem has not received consideration. The separate visibility of regularly ruled lines is by comparison unimportant. The separate visibility of dots and lines (flagellæ) seen in a bright field is a subject the importance of which can hardly be over-estimated. It is in this connexion that the problem of illuminating the object on the stage of a microscope acquires its chief importance. When we begin to deal with objects the dimensions of which fall below the half wave-length of light

---

[1] The Microscope. Part II. A Sequel to The Microscope: a Simple Handbook. By Conrad Beck, C.B.E. London: R. and J. Dick, Ltd. 1924. Pp. 231.

limit, the problem of illumination becomes all-important, and the most serious of the microscopist's difficulties are caused by the faulty lighting which results in glare in the instrument and the flooding of the object with top light. This is a subject which Mr. Beck has taken much trouble to investigate and on which his book contains much original and valuable matter. One criticism suggests itself. Experiments are described in which the author attempts to identify the source of the top light by which dark objects in a bright field are attenuated or even obliterated if the top lighting be sufficiently overpowering. The lenses of the microscope itself are an obvious source of such top lighting and their effect was accordingly investigated, but with a curious result. Mr. Beck sums up his conclusion under this head in the words, "Reflections from the surfaces of the lenses of the microscope do not appear to be sufficient to cause much effect with transmitted light" (p. 110). Now there is one lens surface in the microscope which is, unless precautions are taken against it, a source of perfectly overwhelming top lighting on the stage—that is to say, the back face of the front lens of the objective. It is a large segment of a sphere of which the centre lies in or very near the object on the stage. If the source of light is focused at its centre this lens will re-focus it at the same point with light thrown down from its back face. In the case of a high power lens in which this segment may approximate to a hemisphere and the under face be optically abolished by immersion oil, this focused reflection easily becomes overwhelming. Thus if a small fragment of etched metal be mounted in the centre of the stage, leaving room for sufficient light to enter the lens from the bright field round its edges, it will be seen brilliantly illuminated in this way. It is for this reason that it is found impossible to see a diatom to advantage if the light source is accurately focused in the conjugate plane to the plane of the stage on which the diatom lies. This kind of faulty lighting is equally pernicious when bacteria or other dark objects are observed upon a bright field, and it is a point to which the attention of the medical practitioner, in particular, should be pointedly called. If we are disposed to find fault with the author for having missed this point, it would be necessary to add that Mr. Beck has done more than any other text-book writer to elucidate this branch of microscopic technique.

CARCINOMA OF THE STOMACH IN YOUNG PEOPLE.

IN a paper read before the Southern Medical Society Dr. Raymond P. Sullivan,[1] of New York, devotes his attention to the occurrence of carcinoma of the stomach in the first two and a half decades of life, of which he has collected 21 examples, as well as a case which recently came under his own observation. Although no age is immune, gastric carcinoma is extremely rare during the first decade, only six out of 7000 cases of carcinoma of the stomach analysed by Osler and McCrae being of this age. Four of these were in children under 6 weeks, one was in an infant of 18 months, and one was in a boy of 8 years. During the second decade gastric cancer is also rare, only 13 such cases being found in the series of Osler and McCrae. In the third decade the condition is more common and probably occurs to the extent of 3–4 per cent. Among 50 cases of gastro-intestinal cancer in youthful persons collected by Bernouilli in 1907, the stomach was the seat of the tumour in 13, in 5 of which the pylorus was the part affected. In 3 cases the cancer was supposed to have originated from ulcer of the stomach. Five of the 13 cases were colloid cancers, three scirrhous cancers, one adenocarcinoma, one medullary solid carcinoma, one a mixed type, and in one no statement as to its nature was made. Juvenile gastric carcinoma is characterised by sudden onset, rapid course with persistent high temperature, absence of cachexia, and early metastases. The absence of cachexia is explained by the rapid course, so that the digestive disturbances lead to loss of weight without having time to produce marked wasting. The high temperature is referable to disintegration and breaking down of carcinomatous tissue, the fever beginning at a relatively early stage and persisting until death. Among the important diagnostic aids in these cases other than X rays is the proper use of gastric catheterisation. Operative treatment is indicated in all cases in which removal of the tumour and its immediate metastases seems possible as well as in cases in which the growth has produced stricture of the cardiac or pyloric orifices. Non-operative methods such as irradiation with X rays or radium have not yielded encouraging results. Partial gastrectomy when possible is the operation of choice. Gastro-enterostomy is indicated when radical surgery is no longer possible or in existing or incipient pyloric stenosis in inoperable cases. Dr. Sullivan's case was that of a man aged 22, who had suffered from epigastric pain for four months with loss of flesh, strength, and weight. A provisional diagnosis was made of ulcer of the posterior gastric wall, but on laparotomy the posterior gastric wall was found to be fixed to the pancreas by an irregular growth occupying the pars pylorica and pars media. A partial gastrectomy of a modified Billroth II. type was performed. When seen eight months after the operation the patient was in good condition, no sign of recurrence was found, and the X rays showed evidence of good gastric function and motility.

HOOKWORM SURVEY IN SIAM.

BETWEEN June, 1921, and April, 1923, an extensive survey was carried out in Siam to determine the extent and severity of hookworm disease and other intestinal parasitic infection throughout the kingdom as general data required in the development of a comprehensive programme to control the infection were lacking. The work was done under the auspices of the health section of the Siamese Red Cross Society, of which H.S.H. Prince Vallabhakara is director, in coöperation with the International Health Board of the Rockefeller Foundation, of which Dr. M. E. Barnes is director for Siam, assisted by Dr. H. R. O'Brien. Attention was also paid to the collection of other health data, the stimulation of improvement in sanitary conditions, and the conduct of a general health educational campaign. The final report of the survey has recently been issued.[1] Six survey units were engaged in the work, each consisting of a medical officer and four assistants suitably equipped. Lectures and demonstrations in schools and public buildings were given in order to conduct effective health educational propaganda. Siam is divided into 74 districts (or changwats), in 44 of which investigations were conducted. The kingdom can be divided geographically into four regions. The most important is the great river valley of the Me Ping, whose headwaters rise in the mountain ranges of the north; in the south it narrows out into the neck of the Malay Peninsula. Most of the inhabited area is only a short distance above sea-level and supports a population of nine millions. There is only one large city; the great bulk of the people live in villages of 100–800 residents each. Rice is the universal crop. The prevalence of hookworm varies very markedly in different parts of the country. There are three main centres of infection lying in the far north, the east, and the far south. In the southern districts the incidence of infection is found to vary with the distance from the sea. The infection-rate in Bangkok proper is 8·3, while in Chiengmai in the north it is 81·5 per cent. A complete explanation for these variations in infection-rate awaits further investigation. In this survey campaign 243,930 persons were examined, of whom 7·35 per cent. were found infected. A remarkable uniformity exists throughout the country in the distribution of the various age-groups; the rate rises steadily from infancy and reaches its peak during the period 40–60. Females are only slightly less heavily infected than are males of the same ages. As regards race susceptibility, the Chinese have practically the same infection-rate as their Siamese neighbours; the Indians maintain a slightly higher rate. Of the total population examined no less than 75·8 per cent. are infected with some intestinal parasite, and next to the hookworm, *Ascaris lumbricoides* is the most important. Very considerable attention is being given by the survey units to the question of health propaganda designed to create popular interest in public health matters.

---

DR. KERR'S RETIREMENT.

At the County Hall on Oct. 1st Dr. James Kerr was entertained by a large number of his colleagues past and present, and Sir William Hamer handed to him a memento of the high appreciation in which he has been held as research medical officer to the London County Council. Dr. Kerr entered the service of the London School Board as medical officer in 1902. Before that he was in practice in Bradford, where as honorary surgeon to the Bradford Royal Eye and Ear Hospital and medical superintendent to the Bradford School Board he conducted an active exploration of the possibilities of school hygiene, a field hitherto untouched, using unorthodox but scientific methods of investigation into such questions as vision-testing, estimation of mental ability, and infectious disease. His work in this direction was recognised by the award of the Howard Medal of the Royal Statistical Society for an essay which contained the first reference to congenital aphasia in cases of word-blindness and word-deafness among school-children. On this early work of Dr. Kerr's has been erected the vast structure of the school medical service as it stands to-day. He was also an active member of the Departmental Committee on Physical Training, and took a prominent part in organising the International Congress on School Hygiene, which was held in London in 1907. During the war Dr. Kerr founded and, until he left the service, directed the London Psychological Clinic for treating patients suffering from shell-shock by re-educative methods. He has been for many years a member of the Council of the Illuminating Engineering Society, and was one of the English representatives appointed to the recent International Conference on Standards of Illumination. All which goes to show that in retiring from the routine of office work Dr. Kerr does not intend to lead a life of leisure. We may hope that he will embody his unrivalled knowledge of the principles of school hygiene in some permanent form. We understand that he has not quite severed his connexion with the London County Council, which will still be able to avail itself of his services in a consultative capacity.

PREVENTION OF HEART DISEASE IN NEW YORK.

An account of pioneer work carried on in New York was given recently at a post-graduate medical course in Dayton, Ohio, by Dr. Haven Emerson, president of the Association for the Prevention and Relief of Heart Disease.[1] Dr. Emerson compared the present situation with regard to heart disease to the position which tuberculosis held a few years ago. Organic heart disease is at the present time the first of the killing diseases in America. It is not at present thought of as "curable, preventable, and communicable," yet there are grounds for supposing that to a certain degree all three of these adjectives are applicable. A large proportion of cases result from the rheumatic group of infections, while syphilis is responsible for a growing proportion of the organic lesions arising after the age of 30. Forty-eight heart clinics have been established in the city of New York, cases being referred to them by the general hospitals and dispensaries. Dr. Emerson mentioned that in one children's hospital the amount of "bed time" devoted to cardiac cases had been reduced from 30 per cent. to a mere 6 per cent. by the opening of these special clinics. While the general hospitals are relieved, the patients have the advantage of after-care very much like that given to the tuberculous, and a certain amount of vocational guidance. Two trade schools for teaching appropriate crafts to children with heart disease have been opened in New York. A suggested list of suitable trades for skilled and semi-skilled workers of either sex is published by the Association amongst their educational literature. The Association has also been successful in persuading convalescent homes and summer camps to open their doors to heart cases. These institutions no longer fear the possible complications of a sudden death when the heart cases sent to them have been certified by a specialist in the heart clinic as suitable for their particular variety of institutional treatment.

THE CANCER CAMPAIGN IN NORWAY.

In the October number of the *World's Health*—the review published by the League of Red Cross Societies in Paris—an account is given of the cancer campaign in Norway by Dr. F. G. Gade, who is the secretary to the Norwegian Committee for Cancer Research, and who is well known in Norway as the greatest driving force in this campaign. As he points out, the isolated and stationary character of the population in the country districts has been exploited by the Cancer Committee which has induced many doctors in settled country communities not merely to notify cancer deaths, but also to undertake a study of such subjects as heredity, which require a stationary population. It is interesting to note that cancer of the uterus is very rare in the isolated country districts, and that of all the notified cases of cancer of the lip 97 per cent. involved the lower lip, and as great a proportion as 88 per cent. of all these patients were males. Nearly all these cases came from distant valleys among the mountains, or from forest or coast districts where the clay pipe is still much smoked. It is only since 1919 that the Cancer Committee has succeeded in getting all medical officers of health to give a special yearly report on deaths from cancer in their districts, the scheme of this report being framed by the Committee with 30 different localisations, more or less on the lines of British cancer statistics. From 2700 to 3000 deaths from cancer occur in Norway every year. Cancer, which is responsible for 7 per cent. of all the deaths, ranks after tuberculosis and old age as the most common single cause of death. There are 10·9 deaths from cancer for every 10,000 living persons in Norway. The disease is equally distributed between the sexes, for while 51·8 per cent. of the patients are women, it should be noted that 51·3 per cent. of the total population is female. From 51 to 52 per cent. of all the cases of cancer affect the stomach, and 66 per cent. are found somewhere in the digestive tract. Cancer of the uterus, ovaries, and breast accounts for 12 per cent. of all the deaths. It is doubtful if the growing number of notifications means that the frequency of the disease is increasing, for such factors as improved methods of diagnosis and the greater average longevity of the population may give an erroneous impression in this respect. To facilitate early diagnosis, arrangements have been made at the pathological institutes in Christiania and Bergen for free microscopic examinations of material removed at operation or after death. Several thousand such examinations have been made. A large modern cancer hospital is soon to be built near Christiania, and already two and a half million kroner have been collected for it. It is to be equipped with all the modern means for diagnosis and treatment, and is intended mainly for poor patients suffering from inoperable disease. The Cancer Committee also conducts propaganda for the early diagnosis of the disease.

TYPHUS AND *TYPHUS*.

THE Weekly Return of Infectious Diseases, issued by the Registrar-General for the week ended Oct. 4th, contains an announcement of one case returned as typhus fever, and a cross reference shows that the notification came from the metropolitan borough of Bethnal Green. Dr. G. E. Oates, medical officer of health for the borough, informs us that this case was not one of typhus at all, but was notified from the German Hospital as *typhus abdominalis*, which is the German term for typhoid fever. We are not concerned to inquire particularly how the misunderstanding developed into a slightly alarming entry in the Weekly Return. It may, however, be well at a time when international thought for infectious diseases is overstepping national and political boundaries to make sure of a nomenclature which is generally understood. It is now long since with the aid of Jenner and Murchison a group of dangerous febrile illnesses of long duration was finally split up into typhus and typhoid, and it was, no doubt, wise to introduce names of markedly distinct tone. The word *typhus*, however, continued to do service in the German-speaking countries for the whole group, a qualifying adjective being added: *abdominalis* corresponds to our typhoid; *exanthematicus* to typhus fever; *recurrens* to relapsing fever. It would probably be a safeguard for us also to qualify the term typhus with the adjective exanthematic and so, as we become more polyglot, avoid a source of confusion which has here shown itself in high places. It is the less to be regretted that the Nomenclature of Diseases issued by the Royal College of Physicians of London in its latest edition dropped the foreign equivalents, since its place may be filled by the International List of Causes of Death, revised at a Paris conference in 1920.

THE CLINICAL THERMOMETER AS NOXA.

THERE is a pleasant theory, largely justified by practice, that the doctor lives a charmed life and, as he goes about his daily work, does not become infected himself with the many infective agents with which he comes in contact, nor does he carry these with him home or to other patients. This professional immunity seems also to include that faithful instrument of general practice, the clinical thermometer. We know of no exact inquiry into the usual habit of the practitioner, but no doubt a large proportion simply cleanse the bulb of the thermometer with water or soap-and-water before replacing it in the case. In THE LANCET of August 23rd (p. 406) Major H. C. Brown, I.M.S., demonstrated that this method of cleansing the clinical thermometer is ineffective in the case of intentional contamination with a laboratory germ, and he documented his statement with abundant cultures of the bacillus from clinical thermometers which had been washed in water and wiped with a clean cloth. This is the bacteriologist's challenge. Now, there is every reason that the clinical thermometer should be freely used on all possible occasions, and that no unnecessary formality should stand in the way of such use; experience of general practice is in the final issue the best criterion of how to use it. The practitioner who has to adapt clinical means to clinical ends need only observe the aseptic code in so far as it is of proved necessity. The mouth is evidently provided with efficient measures, whether natural or acquired, to prevent infection of modest intensity. Otherwise what infant would escape whose comforter is replaced in its mouth or what adult who consumes ripe cheese? Nevertheless, more attention should be paid to the avoidance of conveying living germs by the clinical thermometer. Instrument makers have already made it small and convenient for us in a way unfamiliar to the Continent, where a thermometer is often the size of a long cigar; the reservoir has been arranged so that the thermometer reads quickly and the mercury shakes down easily; it is apparently too much to ask for a glass thermometer which can be dipped in boiling water without bursting. The Immisch thermometer, which consists essentially of metal, is as yet a pleasant scientific toy. It is true that manufacturers have of recent years made glass which can be heated red hot and dipped in cold water without breaking, but so long as the constricted neck remains an essential part of the mechanism of the clinical thermometer, any sudden application of heat must continue to burst the bulb. We are driven, therefore, to fall back on the more prolonged action of antiseptics. Antiseptic thermometer cases without number have been devised. One was described in our columns more than 20 years ago, in which the case could be filled two-thirds with strong carbolic solution. Other instruments provide an absorbent lining which can be moistened with antiseptic lotion; the evolution of formaldehyde vapour within the case has also been effected. There are a number of simple devices now on the market, and the St. Dunstan's case,[1] to which we have already called attention, is highly ingenious in conception and quite satisfactory in practice. The practitioner might in many cases, as a correspondent has reminded us, put the onus of providing a clean thermometer on the patient, remembering that a family is much less susceptible to its own bacterial flora. But Major Brown's warning is a word in season.

THE Final Report of the Departmental Committee on the use of Preservatives and Colouring Matters in Food is being printed and will shortly be issued from H.M. Stationery Office. The terms of reference to the Committee have been extended to include the question of the treatment of flour with chemical substances, and the Committee will now proceed to inquire into this question.

A MEETING is being arranged by the Royal Society of Medicine at 1, Wimpole-street, London, W., on Nov. 6th, at 8 P.M., between the Section of Obstetrics and Gynæcology and the Section of Epidemiology and State Medicine and the Society of Medical Officers of Health, to discuss the notification of puerperal sepsis. Those engaged in general practice, who are not members of the Sections and Society mentioned, will be welcomed as visitors and are invited to take part in the discussion, as it is thought to be very desirable that the views of the general practitioner should be put forward as well as those of the obstetrician and medical officers of health.

AT the second session of the Royal Commission on Lunacy the Board of Control was again under examination. Sir Frederick Willis informed the Commission that of the 5525 patients sent out on trial during a recent year a large proportion had to return again to institutional care. The insufficiency of accommodation for mental cases would, he said, in a short time become serious. The Chairman of the Commission remarked that workhouses were not proper places for the reception of patients likely to improve under treatment, a point on which the Board of Control would welcome discussion. In answer to a representative of the National Society for Lunacy Reform, Sir Frederick Willis said that not more than six cases a year of cruelty to patients occurred in which dismissal or other disciplinary action was taken instead of prosecution, and all allegations of cruelty were followed up. The present machinery of certification and detention, he thought, adequately safeguarded the liberty of the subject. Sir George Schuster described the legal position of the Lord Chancellor in lunacy matters. The next meetings of the Commission will be held at 5, Old Palace Yard on Oct. 21st and 22nd, beginning at 10.30 A.M. each day, when evidence will be taken from the Ministry of Health.

---

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XCII.—THE TREATMENT OF HÆMORRHAGE IN THE NEW-BORN INFANT.

THE two main types of hæmorrhage which may be seen in the new-born—true birth hæmorrhage and spontaneous hæmorrhage—are as distinct in their treatment as in their ætiology. Like most affections peculiar to the early days of life these conditions have not received the attention which is their due, considering their frequency and the high death-rate which is associated with them. Without entering into details as to the somewhat obscure ætiology of certain varieties of hæmorrhage, one may mention, as a basis for rational treatment, the forms in which the bleeding may occur in the new-born infant, and their probable origin.

Birth Hæmorrhage.

True birth hæmorrhage is by far the commonest type of bleeding in the new-born. It is now becoming recognised that the underlying cause is the congestion resulting from asphyxia during parturition. In all infants born with asphyxia livida this congestion is well marked, and in the majority some form of hæmorrhage is present. It may be only petechial or capillary, but it may be of a grosser character. Such congestion, with or without hæmorrhage, is often fatal. The treatment is largely prophylactic and consists in the prevention of undue asphyxiation of the fœtus by keeping the duration of labour within reasonable limits. A child which is born deeply asphyxiated, with its heart engorged with blood and all its veins and capillaries congested, can hardly fail to benefit from the withdrawal of some blood from the circulation. Hence good results may be obtained by allowing a few c.cm. of blood to escape from the cut end of the cord. Care should be taken to avoid violent manipulations which might lead to traumatic rupture of vessels in an asphyxiated and congested infant.

Traumatic hæmorrhage may occur either during labour or after delivery. Intracranial hæmorrhage from tearing of dural structures, such as the tentorium cerebelli, is of frequent occurrence, and is so often associated with a breech delivery that the correction of this malpresentation would appear to be the obvious method of lessening the incidence. Difficult forceps deliveries are also responsible for some cases of this form of hæmorrhage, but in others it is difficult to indicate any measure which might have been employed to prevent the occurrence. Gross hæmorrhage may occur into the body cavities from traumatic rupture of deeply congested organs. The best example of this is rupture of the liver—or rather of the liver capsule—which is not infrequently attributable to the use of violent efforts to establish respiration. The Schultze method of artificial respiration is particularly apt to lead to this type of hæmorrhage. When gross hæmorrhage has given rise to increase in intracranial pressure much benefit may be derived from lumbar puncture, repeated from time to time as required. On account of the practical impossibility of localising the lesion with accuracy, surgical procedures are not advisable, though attempts have been made to deal with intracranial hæmorrhage in this way. Hæmorrhage into internal organs is also unsuitable for surgical treatment in the absence of localising signs.

Spontaneous Hæmorrhage.

The terms spontaneous or idiopathic hæmorrhage have been used to describe a variety of conditions found in the new-born, all of which have bleeding as their most striking feature. They are not to be confused with the forms of hæmorrhage referred to above. In any case where doubt exists an estimation of the coagulation time and of the bleeding time will settle the matter, for in spontaneous hæmorrhage these are both definitely prolonged. Some cases of spontaneous hæmorrhage are associated with sepsis, others occur in congenital syphilis, while others again are of such obscure ætiology as to justify the retention of the term *idiopathic* in describing them. Rare forms exist such as Winckel's epidemic hæmoglobinuria, and it is held by some authorities that even true hæmophilia may lead to hæmorrhage in the new-born. The commonest manifestation of all these conditions is bleeding from the alimentary tract—melæna neonatorum and hæmatemesis. Bleeding also occurs into the skin, into the brain, into the abdominal and thoracic viscera, and from the umbilical stump. The chief loss of blood, however, is from the gastro-intestinal tract, and the amount lost is so great as to reduce the child to a state of extreme anæmia which soon proves fatal if the hæmorrhage is not checked.

In the treatment of such infants we have now a remedy which is practically specific. It consists in the subcutaneous or intravenous injection of *whole blood.* This leads to arrest of the hæmorrhage, and, if it has been applied in time, recovery is probable. The use of serum has been recommended by some writers, but the results appear to be much inferior to those obtained from the injection of whole blood. In all cases where it is suspected that the "hæmorrhagic diathesis" exists the coagulation time and the bleeding time should be estimated.

To test the *coagulation time* all that is required is a sharp Hagedorn needle, a pair of watch-glasses, and a small lead shot. These should be carefully cleaned with soap and water followed by ether. A drop of blood is allowed to fall from a needle puncture in the heel into one watch-glass containing the shot, and the second watch-glass is inserted over it to prevent evaporation. Every half minute the glasses are tilted so as to allow the shot to roll. The point at which it ceases to do so is taken to indicate the time of coagulation. Tested by this method the normal coagulation time in the new-born ranges between five and ten minutes. In cases of hæmorrhagic disease the period may be prolonged to half an hour or more.

In the normal child the *bleeding time* ranges between two and five minutes. It is tested simply by pricking the skin of the heel and removing the drops of blood with filter paper as they appear. If they continue to do so for more than five minutes there is an increase in the bleeding time. In many cases of hæmorrhagic disease the puncture goes on oozing for hours or even days.

Injection of Whole Blood.

As soon as the diagnosis is confirmed in this way preparations should be made for the injection of blood.

Subcutaneous Injection.—The simplest method of doing this is with an ordinary serum syringe of about 20 c.cm. capacity. The syringe is sterilised and fitted with a fairly wide-bore needle such as is ordinarily used for intravenous therapy. The arm of the donor is constricted with a tourniquet, the skin is cleansed, and the needle of the syringe inserted in a vein. From 10 to 20 c.cm. of blood are taken into the syringe and the instrument is withdrawn after removal of the tourniquet. Without delay the needle is inserted through the sterilised skin of the infant in the mid-scapular line. The needle should point outwards towards the axilla. The blood is then injected deeply into the subcutaneous tissues. When the needle is withdrawn the puncture is sealed with collodion and the surrounding area is gently massaged for a minute or two. The results of this treatment—provided it is applied early enough—are very satisfactory, and the ease with which the operation can be performed makes it a method of real use to the practitioner.

Intravenous Transfusion.—It is claimed that even better results are obtained, however, by the intravenous transfusion of blood. For this purpose either a large serum syringe or one of the more elaborate forms of transfusion apparatus may be employed. If a syringe is used it should be one of 20 c.cm. capacity, and should contain 2 c.cm. of a 10 per cent. solution of sodium citrate. A cannula with a short rubber tube attached is inserted into the donor's vein and clamped. A similar tube and clamp are attached to the needle inserted into the infant's vein, so that as many syringefuls of citrated blood may be given as the child may be thought to require. A severely exsanguinated infant can take as much as 15 c.cm. of blood per pound of body-weight (L. B. Robertson). With regard to the route chosen for intravenous injection in the new-born infant, it may be noted that the superior longitudinal sinus is the most satisfactory one. For anyone who is in the habit of performing venipuncture it is a simple matter to enter this sinus through the anterior fontanelle. The child, wrapped firmly in a blanket, is placed on a table on its back, the needle is held at an angle of about 25° with the skin, and is inserted at the occipital angle of the fontanelle with its butt towards the frontal region. Another method is to use one of the veins of the scalp which are so prominent in young infants. Unfortunately they are less easily punctured when the child is exsanguinated. If this route is chosen the child is held firmly on the side with its head resting on a sandbag or hard pillow. Pressure with the thumb on the temporal region will bring the veins into prominence, and the needle can be inserted almost parallel to the skin with its butt pointing towards the crown of the head. The arm veins are not suitable for intravenous injection in the infant, but the internal saphenous vein and even the external jugular vein have been used with success.

Precautions in Selecting a Donor.—A word may be said with regard to the choice of a donor. Ideally the blood of the donor should be tested to ensure that the Wassermann reaction is negative, and the blood of both the donor and of the infant should be "grouped." If there is no opportunity for testing the compatibility of the donor's blood, the safest procedure appears to be the injection of the mother's blood subcutaneously, as described above. A very simple method of carrying out the compatibility test is, however, available. A few drops of the infant's blood are allowed to clot in a capillary tube or Wright's capsule. The serum is then separated from it by swinging in a centrifuge. A *large* drop of the serum is transferred to a slide by means of a capillary pipette wet with citrate solution. To it is added a *small* drop of the donor's blood and a cover-slip is put on. If no agglutination of the corpuscles is seen under the microscope at the end of five minutes the bloods may be regarded as practically certain to be compatible.

In addition to the specific treatment described, every care must be taken to conserve the infant's strength by warmth and feeding. If possible, a quantity of fluid (either water or normal saline) should be given by the mouth. This is readily absorbed, and helps to restore the blood volume.

J. N. CRUICKSHANK, M.D., F.R.F.P.S. Glasg.,
Physician to Out-patients, Royal Infirmary; Pathologist, Royal Maternity and Women's Hospital, Glasgow.

THE LATE DR. W. M. EATON, OF BULAWAYO.—Walter Musgrave Eaton, M.B., C.M. Edin., D.P.H. Camb., Assistant Medical Director of South Rhodesia, and medical superintendent of the Bulawayo Memorial Hospital, died with tragic suddenness there early on Saturday morning, Sept. 13th. He was taken ill while motoring on the previous day, and was brought into Bulawayo. Born in Cape Province, Dr. Eaton was 60 years of age, and had earned a high professional reputation in Rhodesia, where he had practised for many years. Dr. Eaton is survived by his widow and three sons.

Address to Medical Students.

INDIVIDUALITY IN MEDICINE.

An Address delivered to the Students of Durham University Medical College at the Opening of the Winter Session, Oct. 6th, 1924,

BY SIR THOMAS HORDER, BART., M.D., F.R.C.P.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

I THINK it highly probable that all that is worth saying upon an occasion like this has already been said. And I have refrained from reading any such addresses as I am now giving because I know so well from experience that if I read what others have said in similar circumstances, I get so discouraged that I am even more conscious than I otherwise should be of my own incapacity. So what I shall say to you to-day has at least the merit of being my own thoughts, and it would, after all, be a sad commentary upon my use of the opportunities afforded by medicine if 30 years of teaching and practice found me barren of any reflections that are worth telling to an audience like this. I feel that the chief risk I run is regaling you with a string of platitudes—saying things with a solemnity of utterance that are really distinguished by nothing save extreme tenuity of thought. If I warn both you and myself of this possible disaster I may at least avoid the extreme degree of it.

Let me consider, first of all, what it is that you have chosen as your profession. In the Middle Ages the schoolmen did not regard medicine as one of the "liberal arts and sciences." That was probably because in their day medicine was no longer an art, and still less a science. I say "no longer" because it is clear both from literature and from archæology that medicine was a very well-developed art a thousand years before the time of which I speak. But in Chaucer's day it had ebbed so low that it had become something less even than a craft. It was artful, but devoid of art. Nor did it become an art again until science had its renaissance. Then, with the re-birth of anatomy, physiology, physics, and chemistry, medicine became both a science and an art. It has continued to be so. I should perhaps scarcely be challenged if I said that it has become the most liberal of all the arts and sciences, that is, the most worthy the pursuit of a free man.

I have wondered what it was that enabled medicine to survive during that long period when its art was forgotten and its science was not born. I can only think that it was the person of the doctor that kept medicine alive; that the men who set themselves apart to alleviate human ills supplied in place of the knowledge they lacked and the art they had no chance of studying an individuality that appealed to their distressed patients and somehow served a useful purpose. They were certainly men of learning, most of them, and close contact with their fellows in all manner of experiences probably brought them a wisdom which was rather above the average. It was, no doubt, that sort of wisdom which we term judgment and which, if we have it not in medicine, though we "know all mysteries and all knowledge," we are nothing. They would learn patience, too, these men, and courage, and understanding, and, most of all, they would get to love their fellow men.

PERSONALITY OF THE DOCTOR.

Although the idea has gone a little out of fashion, I think this same element of personality is still essential in the doctor if he is to achieve the purpose for which he stands. I do not mean merely that he shall possess certain natural characteristics which are pleasing and acceptable to the ill person, though these, too, are of service and are by no means to be disregarded. A good presence lends a credence to a hopeful prognosis, and a cheerful countenance sometimes saves a patient from despair. I was once leaving the sick-room of a powerful young international footballer who was ill with pneumonia. All the signs were in his favour, and I had no anxiety about the issue. Imagine, therefore, my dismay when he called me back to his bedside and asked me in a hoarse whisper, "Is there a fighting chance, doctor?" His terror was due, not to his own condition, but to the doleful face of his medical attendant. Patients choose their doctors for all sorts of reasons, and none of us can afford to scorn Nature's gifts on the physical plane. "Tell me, Mrs. Smith," I once asked, rather reflectively, a lady who was giving me some breakfast after a very strenuous night spent with the family doctor in keeping her husband alive, "tell me, what led you to choose Dr. Jones for your new medical adviser?" They were old friends of mine, and they had gone to live in a new district. "Oh," said Mrs. Smith, "you remember, Sir Thomas, we are musical, and Dr. Jones has such a fine tenor voice."

Then there are in some doctors natural tricks of manner that attract. Some doctors manufacture mannerisms; they are not such good assets as the natural ones, and I do not recommend them. And yet they sometimes succeed. Since Abernethy's time one occasionally sees a medical man adopt a brusqueness of behaviour which tells with certain patients. Speaking of his wife's doctor to me one day a friend said, "My wife trembles when she hears his foot on the stairs," and learning this I understood, for the first time, her great confidence in him.

But when I speak of the personality of the doctor, I mean more than all these things. I mean the personality which is the outcome of a concentrated and developed individuality. Every man's individuality is a new factor in the universe, a contribution to life and, in the case of the doctor, a contribution to healing. This individuality, which you decide to devote to the high purpose of medicine, is the thread upon which you string the beads of observation, of experience, of patient work, and of sound training. These things by themselves, valuable though they are, do not fit you to be a good doctor; but when they are transmuted through you, when they are dissolved in the general solution of your life, they crystallise out as an influence which brings health to the sick and comfort to the unhappy. I do not think I can get nearer to my meaning than that. This ideal is a high one, making the doctor a priest as well as a physician, and yet it is not higher than the ideal laid down for our profession by the Hippocratic school two thousand years ago: "With purity and with holiness I will pass my life and practise my art." Doubtless you remember these words in the immortal oath.

Worldly Success.

There may be some who are thinking: These highfalutin' considerations are all very well, but the question really is, can one make a success of the thing, worldly success, that is—because a man must live—will the thing pay? Well, I think I can promise you that you can always earn a modest competence at it, a minimum wage—yes, even accepting the present-day notion of a minimum wage—enough money, that is, to keep you free from anxious care, always assuming your needs are few and your tastes simple. I do not think I have ever seen a qualified medical man in pecuniary straits except as the result of ill-behaviour, or foolish speculation. But I am not going to promise you more than this, because whether you become rich or not will depend upon quite adventitious things. For example, some of you may possess business acumen. If you do, you will probably make medicine pay, just as you would make any other calling in life pay. Then again you may find yourself in charge of a very large panel practice. Or you may become an eminent surgeon, being endowed with hands of such singular dexterity that it seems a pity not to use them very frequently. You will most likely earn quite a large income. If, in addition, you are gifted with that valuable asset termed "a good address," you certainly will, for few whose complaints are amenable to surgical methods—and whose are not?—will long escape your siren influence. Then once more, you may be attracted to some new vogue in medicine, something that so tickles the public fancy that, leaving all other doctors, they flock to you to be healed. You will thrive. But in this last instance you must make haste to exploit the new remedy whilst it is still new; and it may be just as well to study the next "stunt" in advance during the few spare moments that a busy practice gives you, so as to be ready for a quick change as soon as the fashion alters. But Durham graduates will not be found in this last category. I can, as I say, promise you that well within the limits of conduct that an honourable man imposes upon himself you will be able to discharge all the pecuniary obligations of citizenship by the practice of your art. As for riches, my friends, if you are attracted by them you have chosen your vocation very foolishly. Sydenham, the father of English medicine, summed up the situation admirably when he said, "But if any think that riches, got by such a reputation, has in it somewhat more of solidity, let them enjoy what they have scraped together with all my heart, but let them remember that many mechanics of the most sordid trades get and leave more to their children." And one might add in these days that if you want to grow rich by dabbling with medicine, you will not get qualified at all. You will, of course, be careful to keep to the windward of the law, and your friends and patrons will think you are ostracised by the profession, and prevented from entering the ranks of the regular practitioners by sheer jealousy. It will all be a gorgeous advertisement. Politicians and dignitaries of the Church and county squires will demand that you be given a diploma or an honorary degree—which is, of course, the last thing that you want. You will engage in bloodless surgery (beneficent sound!), or cheiropractic or the laying on of hands. And you will flourish as the green bay-tree.

It may be that some of you are still wondering if you have chosen well in taking medicine for your vocation. If so, I sympathise with you most heartily. I still wonder myself at times, and it is one of the grievances I have never ceased to allow myself, that there never seemed a good opportunity between my preliminary science studies and embarking upon the subjects of the first M.B., nor again when the time came to change those for the medical and surgical wards, when I could go apart, as it were, and thresh out thoroughly the question of my fitness for medicine. For I was brought up to believe that medicine required special gifts and a definite leaning towards it on the part of the disciple. But for your peace of mind I advise you to leave all this heart-searching alone. From all I see of good and bad doctors—though heaven forgive me if I ever claim to be a judge—I am led to believe that the die is cast long before the decision to study medicine is taken. Perhaps it is cast no less certainly for all avocations in life. I do not suppose for a moment that the poet is the only creature who is born and not made. I am sure I have quite a number of friends amongst laymen who would make excellent doctors, and I occasionally meet a medical colleague who makes me wonder a little if some other branch of human activity than ours has not lost a leading light. I do not think it is possible for even the best observer of character, or rather of temperament, in the boy or girl, to be certain of these things beforehand—no, not even the boy's or girl's own mother!

A Field for Free Activity.

Whether you are going to function well or indifferently as a doctor, there is no doubt, as I said just now, that medicine affords a very good field for the activities of a free man, and this whatever his bent turns out to be. Does he desire large commerce with his fellows? Medicine gives him this in full measure.

Is he attracted by the operation of law in the scheme of nature? He will find ample scope for the study of it here. Does he love beauty, in form or in design? This also is here. Does he crave for sport? In medicine he can track down his game, no less exciting because it is very small rather than very big. Does he delight in stratagem and tactics? Here he can decide how the enemy is to be defeated, where to mobilise and combine his forces. Medicine provides a life alike for the scholar, the recluse, the man of action. Some of you will branch off into physiology, some into biochemistry; some will probably settle down in the bacteriological laboratory as a permanent pursuit; some will marshal an army of preventive measures against epidemic disease. Work in all these fields is of vast interest to the worker and of enormous importance to medicine. I am not, however, concerning myself so much to-day with those of you who will take up these special branches as with the main body, who will leave their alma mater and go amongst men and women to heal them of their diseases. To return, then, to this question of good doctors. Of course, you know already that the ease or the difficulty you experience in passing your examinations is no guide to your future success. So you need get neither cheered nor disheartened on that account. We are all familiar with the man or woman who scores heavily with an examination paper, yet can scarcely say boo to a goose in the sick-room. But I remember the man I coached for the longest time when I was a demonstrator. I coached him so long that I feared for my reputation, and declined to coach him any more. Then I yielded to his father's solicitations, and coached him again, a little fascinated, I think, by the peculiar difficulty of the case. Twelve years this particular "chronic's" curriculum lasted, but at length the Society of Apothecaries received him into its Hall. My pupil turned out to be a most excellent doctor and a very successful one. When I saw him a few years after he left hospital, he had an assistant and a very thriving practice. Nor do I attribute his success to his having married the undertaker's daughter in the town where he set up his plate. I attribute it rather to a considerable knowledge of the world, an unvariable courtesy, a cheerful manner, a gentle voice, and a resourceful mind. In the hospital wards I have seen him talking familiarly with the old folk, and little children, when he approached them, would drop their dolls to smile at him.

So do not think too seriously about those examinations. I know what a nightmare they can be, and how many of the best opportunities of your student days are irretrievably lost on account of them. I wish we could do without them altogether; but they seem to be a necessary evil. You must do all you can to banish the paralysing fear that they create in the mind. Try and believe that, more and more, the examiner concerns himself to see that your methods are good, rather than that your diagnosis is correct. He knows from long experience that, given good methods, all else is bound to follow. So I would say to you who are beginners: Watch your teachers' methods; what they *do* is more important even than what they *say*. Note how they approach the case and how they handle the patient's mind as well as his body. Note also that it is always with them eyes first and much, hands last and little. See how thoughtfully and how patiently the history of the patient's complaint is taken. A good history takes the experienced observer a long way on the road to a diagnosis. Be accurate with your facts; avoid loose terms of speech: "nearly" and "about" and "I think" are the stigmata of a lazy mind. Don't say the temperature is very high, or the pulse rather slow; say the temperature is 105·2° and the pulse is 66 to the minute. Do not forget that the best introduction to the study of medicine is a primer of logic. And, though your reading is important, remember that the patients are more important still. In the words of Trousseau, "Il faut voir, toujours voir, des malades."

The Crowded Curriculum.

The medical curriculum is much too crowded; your teachers lament the fact quite as much as you do. Any one of them has just got time to help you to use terms correctly and to begin to observe when you are whisked off to a colleague for tuition in another subject. It would be good to teach you how to think, but there is no time. I should like to see some unloading of this overburdened curriculum, but so far the powers that be give no sign. Something seems to bar the way; vested interest perhaps. Subject after subject has been added, but nothing seems to have been taken away. Perhaps nothing should be taken away, but rather a drastic revision of the early subjects be made. For it is clear to me that the place to unload is at the beginning and not at the end. Although in a sense it is not your problem, yet you will, perhaps, forgive me if I tell you my ideas on this subject. Moreever, I may not get so good an opportunity again! The revision should, in my opinion, be undertaken with the idea of making everything concentrate upon the study of the sick person. I would teach students to examine blood in the physiological laboratory by the same method used in the wards, and I venture to wander from my own strict province and suggest that the jugular vein might be exposed in the rooms by the same dissection used by the surgeon to tie it in life. I would pursue the same plan in relation to all functions and all structures. I sometimes wonder if it has been a gain to the teaching of students that we have pure physiologists and pure anatomists at the head of these departments instead of physicians and surgeons as formerly. I should be very jealous of including anything in the preliminary subjects which cannot be dealt with in such a way as to have a direct bearing upon clinical and pathological work. I would familiarise the student in the physiological room with several methods and instruments which he will use in the wards, but which, if I may judge by my own experience, he rarely masters properly—the ophthalmoscope, the laryngoscope, the stethoscope, and blood-counting instruments. Is not the fundus occuli a natural object for study, and how does one see it except with the ophthalmoscope? But if I ask my clerk to look at an example of optic neuritis he excuses himself and says that he has not yet "done eyes"; yet it is quite likely that he knows a great deal about the theories of colour blindness. When a student arrives at the stage towards which all his studies should tend, and begins to practise, would it not be a good exchange, to have omitted a study of the minute structure of the organ of Corti, and to have learnt how to see the membrana tympani clearly? I would introduce the simpler principles and methods of bacteriological technique into the teaching of physiology. The student knows all about the presence of a minute trace of potassium sulphocyanide in the saliva, and how to test it—an old and valueless fact; but quite often he cannot tell you anything at all about the bacteria in the same secretion, though these have an importance in his work which nothing can exaggerate. And so also with the flora of the normal fæces; the subject is regarded by the student when he enters the wards, and long afterwards, as a mystery, and knowledge about it is deemed a perquisite of the bacteriologist.

Neglected Subjects.

In some way or other I would modify the first part of the medical course so that the student is better material when he enters the wards, out-patient rooms, or post-mortem room. If he is better material he will learn more readily and make more use of his opportunities, and this will be equivalent to a gain of time for these, his most important years. And he badly wants more time. He wants it, not only to relieve the congestion during these years, but also because there are two or three subjects that have lagged considerably behind the times and are in need of recognition.

1. One of these subjects is *dietetics*. It is an astonishing fact that in this country—perhaps more

than in any other—hundreds of doctors are qualified to practise every year with little more than two ideas about diet. One of these ideas is a remnant of their physiology days, when they were taught the five ingredients of food essential to life; and the other idea—whose origin I do not know, it is certainly legendary—is the fixed belief that if a patient is acutely ill, whatever the nature of his malady, milk is the thing to feed him on. Now, the first of these ideas is not of great practical value in the treatment of disease, because Nature has anticipated the physiologist in her instructions. The second idea does sometimes fit the case, but it gets so strained in its application at other times that the results are frequently somewhat disastrous. Whatever the ultimate outcome may be of the present interest shown in "toxic idiopathies" and in "vitamins," there will be at least one important issue, and that is that more attention will be given to diet in disease.

2. The second subject which I regard as demanding more attention in the compulsory part of the curriculum is *Infection*. Not that smattering of bacteriology which is nowadays required of the student at his final examination, but a proper enlightenment on the sequence of changes taking place as the result of interaction between an infecting organism and the body tissues and functions. Considering the enormous importance and the great frequency of these events, it is, once more, astonishing how little room is given to the subject in the medical course. There is to-day an accumulation of important facts—the theories may be omitted—in this connexion which the student should be required to know.

3. The third subject that lags behind is *Psychology*. I doubt if psycho-analysis, as we see it, would have arrived had the practitioner recognised the importance or been capable of investigating the psychological side of his patient's case. And I feel quite sure that the only cure for the more pseudo-scientific aspects of psycho-analysis will be the inclusion, in recognised form in hospital practice, of psychological methods. It is rather strange when we come to think of it, that we teach the student elaborate physiology of many functions of the body that are relatively unimportant, and entirely omit to teach him any physiology of the most important function of all—namely, the mind. The practitioner, in many instances, learns these things for himself, but only after much painful experience; and even then he misses the great advantages that might be given him by inclusion of elementary principles.

PRIVILEGES OF QUALIFICATION.

And now let me suppose that you have finished all this preliminary training, and that you have satisfied your examiners that you are ready to begin the more serious study of medicine proper. In other words, you are qualified to practise. With the granting of your degree certain privileges are accorded you: you may sign a death certificate, you may sue for fees in a court of law, you are excused attendance upon juries, and your horses may not be taken for the fire brigade. Since none of us keeps horses any longer, the last-named ancient exemption, obviously framed more in the interest of the public than of ourselves, scarcely interests us. Non-attendance of medical men upon juries seems clearly to have resulted from the frequent interruptions suffered by learned judges owing to the doctor being summoned for some sudden emergency, and therefore this privilege again is a benefit for others rather than for us. To sue for money that one has earned, and to get justice, is no more privilege that is expected by every citizen of a properly governed community. This benefit appears to have been specified because *un*qualified practitioners may *not* sue for fees. But inasmuch as these gentlemen always take care to be paid for their services in advance, the benefit is actually more in their favour than in ours. Signing a death certificate is asking for all sorts of trouble, for the doctor who signs one may at any subsequent time find himself called upon to swear to all the particulars in a coroner's court. On the other hand, having signed it, there is no compunction whatever on the part of the coroner to accept it. This state of things is recognised to be so anomalous that a medical man is under no compulsion to sign a death certificate at all. Nor do I suppose that any wise man ever would, were it not that declining to do so places the friends of the deceased in an impossible position. For the same law which has made no proper provision for the certification of death, on the one hand demands that the undertaker shall not function without it, and on the other compels the friends to dispose of the body, in which, to make matters still more confusing, it is specifically declared there is no property.

So much, then, for the "privileges," euphemistically so-called, accorded by law to the qualified medical practitioner. With all the legal privileges the other way the wonder is that anyone takes the trouble to get qualified at all!

Vain Argument.

But, anyway, here you are at length with your well-earned degree. Its registration at least gives you some legal cover in case of accidents, provided you can satisfy the court that you have exercised "reasonable care and skill"—and the interpretation of the word "reasonable" need not give you over much concern. I think you are, in actual fact, and take you all in all, perhaps the best educated and best trained man amongst your fellows. But you must not think that this will be generally recognised. On the contrary, quite a large number of people, who have had no training at all, will argue medicine with you both in its art and in its science, and will treat you as though you have no expert knowledge whatever. They will quote their equally lay friends, and books written by equally lay authors, proving conclusively a large number of "facts" that your teachers and you yourself know to be the wildest imaginings. And they will express surprise that you are so out of date. "What, you haven't read Mr. Knowall Things' book on cancer, in which he proves that if you keep yourself fit and attend to your bowels you won't get the disease?" "No, who *is* Mr. Knowall Things; hasn't he written about economics or something?" "Yes, but don't you think, doctor, that he has studied this question thoroughly?" "No," you will say, "I'm afraid I don't. You see, the problem of cancer isn't touched by a recital of all these trite details of your author as to the value of fresh fruit for breakfast and the avoidance of constipation. The problem of cancer is not why it affects the unhealthy, but why it attacks the healthy. But if Mr. Knowall Things really wishes to benefit humanity let him hand over the proceeds of his book to the British Empire Cancer Campaign, or some equally good organisation, so that men who are properly trained and equipped for research may get on with the problem." Then there is Mr. Blank, the distinguished novelist, and Mr. Nought, the playwright, and there is an eminent divine, and a politician, and a newspaper proprietor—all of them ready to tell you exactly what is wrong with your patient, and exactly what should be done for him, even if they are not writing books and articles on the exact causation of what are to you obscure diseases. Well, you must never lose your sense of humour; you must remember that all this is part of the comedy of things. There is even food for psychological study in it, for underneath all this misdirected interest in the diseases of their friends, in disease in general, and especially in cancer, does there not lurk the unacknowledged fear that the dread scourge may some day count these folk amongst its victims?

EXIGENT PATIENTS.

Since you will find your time very fully occupied with your work, and since it is my duty to help you to save as many "grains of the golden sand" as possible, I advise you to learn early how to give all these people a short shrift; you will then have more time for those choice spirits who actually consider that you know more about diseases and their treatment than they do, and also for these tiresome folk too, when they themselves fall ill and need you. You must be so jealous of your time that you will grudge it for another class also, and that is the people who would like you to live their lives for them. They do not, of course, put it like that when they come to see you, but that is what it amounts to. Of course, you cannot do it, and it would be very bad treatment if you could. It is a law of our existence that every one of us must live his or her own life separately. Merging our being in that of the doctor is not life but parasitism. Some of these patients you will find have no exigency in their day, and without exigency none of us can be healthy. Exigency you will find to be an invaluable prescription. To have to do something at 9 o'clock every morning, which, not being done, you are yourself (if you are selfish), or your friend (if you love him) is left hungry or unhappy—that is apparently one of the laws of health. Well, these patients whom I have in mind do not conform to this law, and they fall ill, and they come to you because, as they say, they have heard how clever you are. They have already seen many doctors and they have had many treatments, and so far no one has been able to diagnose their case. They are so anxious to be well and like other people. And they finish by saying, "What are you going to do about it, doctor?" In as kindly a way as possible you explain that there is no "it," and that *they* and not *you* must do things about it if they really want health. Some of them have got into a tangle with their emotions, or their undisciplined emotions (for their mothers were often as foolish as they) have landed them in a hopeless mess with their affairs, domestic and otherwise. The symptoms they relate, and the obscure disease they attribute their unhappiness and unfitness to, are but an unrecognised disguise for an emotional stirring that is still unsatisfied. Some of them really do suffer from a slight, perhaps physically incurable, handicap which is enormously overloaded in their mind by a nexus of depressing, though mentally absorbing, ideas. They memorise ancient troubles: the operations they have had were the most difficult of their kind the surgeons ever had to perform; their diseases had all the known complications and some others; recovery was several times despaired of; "so it's not surprising, is it, doctor, that I suffer so much?" Again you try to be of help, though experience soon teaches you that it is not certain f, in some of these cases, help that is successful would be welcomed. Anyway, it is always *you* who must do the energising and the activating. I was explaining to one of these patients recently that, in my judgment, it was her attitude towards her trouble hat required altering rather than that the trouble tself needed attention. To which, with a look of complete confidence in my discrimination, and with a bland smile, she said, "Will you *treat* me for my attitude, doctor?" Lastly, there are the patients who have not made up their minds if it is better to be well han ill. You must get the decision clearly and convincingly made before you embark upon treating these.

LAWS OF CAUSE AND EFFECT.

My advice to you is to tell your patients as clearly s you can why they are ill, be the illness physical or mental. Point out to them that certain results have ollowed the operation of the laws of cause and effect, nd that these results are the things they wish you o relieve. It is sometimes necessary to remind them ow immutable, how inviolable, are these "Chancellors f God" as Emerson called them, adamant if broken, ut beneficent if obeyed. Tell them how best they an re-trace their steps and help them all you can. But do not argue with them, or get heartaches because hey do not take your advice. That you are bound to do, f course, at first, but it is a juvenility that disappears ith the years. I tell you these things because I want o save time for you if I can, and I wish to get you o maturity earlier in your career than I am doing. he sooner you mature the greater your value to the orld. Do not think me cynical about certain types f patients. Thank God, they will be in the minority. That is, unless you prove to be one of those persons who possess a subtle attraction for the tiresome people I have mentioned. Then my best advice to you is to take long and frequent holidays and to go abroad for them. And you should put on duty the colleague who is the keenest golfer in the district. No, most of your patients will really need your help, will loyally observe your advice, and will try hard to regain their health. You must give them all your knowledge, all your skill and all your time ungrudgingly. Some of them will rely upon you; to these you must give yourself in addition, for these you must, if necessary, sweat blood.

What experiences will you not have! What wealth of material for the study of human nature will you not meet! In what unique situations will you not find yourselves! In all these things you will, if you are wise, still be the student and still the observer. You will watch the play of men's passions: love, envy, avarice; you will see the havoc these elemental forces can wreak upon their physical as well as upon their moral health. You will meet men and women whose cases puzzle you until you realise that they are ill because of a fruitless remorse or because of a baffled ambition. You will discover that there are, after all, such things as broken hearts, though there are no "physical signs" of disease, and "graphic records" point to no defect. You will see men enervated by the intoxication of success or stimulated to robust health by the smart of failure. You will be able to trace association between physical and mental idiosyncrasies on the one hand, and domestic relations, business habits, political exigencies, and even religious emotion on the other. You will often be able to interpret men's weaknesses, and your knowledge will make you charitable; you will sometimes understand their strength, and your insight will increase your admiration. The streak of genius that attracts your worship will also evoke your warning. You will be privileged to add not a little to the world's progress and happiness by steering the activities of some who are but poor navigators of their own ship, yet who carry a precious freight, whether it be the power to lead men wisely or to charm away their griefs.

THE TRIUMPH OF PRINCIPLES.

You will find medicine a jealous mistress, but you have chosen her, and if you serve her loyally she will return your devotion in full measure. This does not mean that you will lead small, ignoble lives. You will follow George Wyndham's dictum: "If we cannot make our lives long, let us make them broad." Indeed, that is a part of your duty. You will need all the antennæ that you can develop so that you can touch people at many points. All this you can do and still be your self, made wise by fusion with life, so that you become an artist and not a mere technician. In your work, however, though you will be tempted to diffuse, you must concentrate. Politics, literature, art—each one will say to you, "Come out and try us," but you will decline. More subtle will be the temptation to stray into some by-way of medicine itself, something that promises the panacea that men crave for. You will resist this also. You will be chary of the short cut, the royal road, and the leap that science, no more than nature, never takes. Always you will keep an open mind. It will be well if you add to your daily prayer: "Save me from obsessions." You will remember that, just as in life nothing can bring men peace, so in medicine nothing can bring them health, but the triumph of principles. This thought reminds me once more of Sydenham, and I cannot more fitly end these remarks than with another quotation from him. He is concluding his "Epistolary Dissertation," and he says, "And now, worthy Sir, I desire you to accept this small treatise favourably which was designedly written to return you thanks for your approbation of my other works. And indeed, I have so seldom received anything like approbation, that either I have merited no such thing, or else the candid and generous men whom nature has framed with such excellency of mind as to know how to be grateful, are very few, ... yet, notwithstanding, I endeavour all I can and will do so, to learn and promote the method of curing diseases, and to instruct those who are less conversant in practice than myself, if any such there be. Let other people think of me what they please. For having nicely weighed whether it is better to be beneficent to men or be praised by them, I find the first preponderates and most conduces to peace of mind. As for fame and popular applause, they are lighter than a feather or a bubble, and more vain than the shadow of a dream."

Special Articles.

SCOTLAND.

(From our own Correspondent.)

St. Andrews Institute for Clinical Research.

At the opening of the winter session Dr. Maitland Ramsay delivered his inaugural address as Director. There was a large attendance of practitioners from Fife and from Dundee. Dr. Ramsay referred in grateful and feeling terms to the founder of the Institute, Sir James Mackenzie, and expressed gratification that though he was no longer present his name was still associated with the Institute as its President. He dealt with the general principles of clinical research as enunciated by Sir James Mackenzie and with the fact that the general practitioner has continuous opportunities of furthering the knowledge of disease by clinical observation in his practice. He particularly emphasised the importance of clinical observation and commented on the tendency to neglect this primary function of clinical medicine and to rely upon laboratory reports in its stead. While these were of inestimable value they could never replace that accurate observation and weighing of clinical symptoms upon which the older physicians relied. The value of the sensations experienced by the patient was often underestimated, but as a clinical ophthalmologist he could assure his audience that these were of the utmost diagnostic and prognostic significance in diseased conditions of the eye. He drew a close parallel between the symptoms of eyestrain and the sensations and disabilities experienced by patients suffering from cardiac inadequacy. Dr. Ramsay hoped that his audience would take full advantage of the facilities of the Institute for recording their observations. Dr. C. E. Douglas (Cupar), secretary of the Fife Medical Association, urged his audience by their coöperation to ensure the continued success of the Institute.

Royal Medico-Chirurgical Society of Glasgow.

The opening meeting of this Society was held on Oct. 3rd, when Prof. Archibald Young delivered his presidential address on the Limitations of Surgery, Past and Present. In introducing his subject the President declared himself to be far from taking a gloomy view in his outlook on surgery as, perhaps, the title might suggest. Rather was his aim to indicate the directions in which surgery as a science might progress and the lines along which further research might most profitably be pursued. In the course of a short historical survey of the earlier surgical achievements he referred to an interesting address by Erichsen in 1886, in which the following pronouncement occurred :—

> That the final limits of Surgery have been reached, in the direction of all that is mechanical and manipulative, there can be, I venture to think, little doubt. . . . We have thus reached, in many of our most important operations, the final limit to which Surgery can be carried. . . . Art is final, but Science is illimitable We have reached finality in the mere mechanical Art of Surgery, both as to the expansion of its limits and the precision of its practice. But we are yet on the threshold of the Science of Surgery.

While such a pronouncement, said the President, made over 40 years ago, and by one of the foremost surgeons of that day, could not, in view of the notable advances in operative method and technique since that time, be accepted as even approximately correct, it contained, nevertheless, more than a grain of truth, and it emphasised the separate rôles, and the very different outlook of surgery, the purely technical art, and surgery, the science. The field of cranial surgery was chosen to illustrate some of the victories over the restraints and limitations which had rendered progress difficult, if not impossible, and reference was made in particular to what were perhaps the greatest of such victories—namely, the discovery and elaboration of anæsthetics and the conquest of microbic infection by the introduction of antiseptic practice and technique. The President then outlined a few of the limitations that yet remained to hinder the advance of the science of surgery—the problems of repair of tissues—the manner in which the organs functioned, and the question of periodicity as a fundamental mode of action—tumour growth—the action of X rays, radium, and irradiation, and many other such problems, and urged the necessity for combined research by all concerned. "Before we can hope to set aside materially the restraints and limitations that still remain, we shall have to adopt all sorts of lines of research. We must adopt in the most unselfish spirit a generous and all-embracing system of collaborative research, by which the experience, enthusiasm, original thought, and varying points of view of many workers, not only in pure surgery but also in all the allied sciences, may have cumulative weight."

Welfare of the Blind.

The second report of the Scottish Advisory Committee on the Welfare of the Blind [1] which has just been issued covers the period 1921–24. It is signed by Sir David Paulin, chairman, and Major Sir William Reid, vice-chairman, on behalf of the Committee, which includes representatives of public authorities, voluntary agencies, and blind workers. This Committee was set up shortly after the passing of the Blind Persons Act, 1920, to advise the Scottish Board of Health on the care and supervision of the blind in Scotland. There are, the report states, 6054 blind persons in Scotland on the Central Register kept by the Board of Health. Of the total number of registered blind, 399 are under 16 years of age and 3627 are over 50. (The latter, in respect of age, are eligible for blind pensions.) The Committee record with pleasure the striking decrease in the number of blind children under 5 years of age, from 48 in 1920 to 15 on April 1st, 1924 ; 3650 blind persons, or 60 per cent. of the total number of blind in Scotland, are unemployable. The report discusses and makes recommendations on many varied subjects, recommendations which have been extensively adopted by the Board of Health and are now the accepted policy in Scotland. On the question of municipalisation the Committee state, "The general view held by us was that municipalisation of institutions for the blind was a question for the future rather than for the present. The view was also expressed, however that the passing of the Blind Persons Act was an admission of the failure of voluntary effort, and tha provision for the blind should be made entirely by public authorities and not be left to charity. By majority we agreed to recommend that as a genera principle the municipilisation of workshops for th blind is not at present desirable."

Amending Legislation.

The Committee disapprove of the Blind Person Act (1920) Amendment Bill, as drafted, and the submit an alternative scheme of amending legislation. In the Committee's opinion new legislatio must deal principally with the problem of the unemployable and necessitous blind. They recommen that a graduated compensation allowance of no less than £1 a week should be granted to blind person within a prescribed means limit and that this allow ance should be paid to the capable and incapable blind alike. The graduated scale starts with the maximum allowance of £1 a week where the means of the blind person do not exceed £105 a year and ends where the means exceed £199 10*s.* a year. The Committee recommend that two-thirds of the cost of the compensation allowance should be met by the State and one-third by the local authorities, and they estimate that the net additional annual charge for Scotland, on the basis of £1 a week compensation, would be £113,000 on the State and £86,000 on the ocal authorities.

Post-Graduate Medical Teaching in Glasgow.

The teaching scheme of the Glasgow Post-Graduate Medical Association is divided into three groups—namely, weekly demonstrations, special courses, and clinical assistantships—and the syllabus for the forthcoming winter session has just been issued. The series of demonstrations at the various hospitals on Wednesday afternoons has been arranged on similar ines to those of former years. Three special courses will be held on medical ophthalmology, conducted by members of the staffs of the Eye Infirmary, the Ophthalmic Institution, and the general hospitals; on the Mother and the Newborn Infant, under Prof. J. M. Munro Kerr, Prof. Leonard Findlay, Dr. S. J. Cameron, Dr. James Hendry, and Dr. J. N. Cruickshank; and on Fractures, under Mr. George H. Edington and Mr. Charles Bennett. A limited number of clinical assistantships, for periods of hree months, is available at certain of the institutions taking part in the work of the Association. Copies of the syllabus and further particulars may be had from the Secretary of the Association, the University, Glasgow.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Royal Academy of Medicine in Ireland.

THE annual general meeting of the Royal Academy of Medicine in Ireland was held last week. Sir James Craig, King's Professor of Medicine in the School of Physics, was elected president. Prof. F. C. Purser was lected president of the Section of Medicine, Mr. R. C. B. Maunsell of the Section of Surgery. Most f the other officers are unchanged. The report of he council for the year 1923–24 stated that during he session 1923–24 the Academy consisted of 193 Fellows, 13 Members, and 26 Student Associates, an ncrease of 20 Fellows and 6 Members over the previous ear. Having noticed the loss by death of three onoured Fellows, Wallace Beatty, Alexander C. O'Sullivan, and Sir Andrew Horne, the report records hat the urgent need for the provision of facilities in Dublin for research in connexion with medicine and the llied sciences had been brought before the council. A conference of the various licensing corporations in reland was invited to meet the members to discuss the matter. At that conference a scheme for the establishment of a research institute was drafted, and the draft as been submitted to the various corporations which were represented. As soon as the approval of hese bodies has been received it is proposed to ubmit the scheme to the Government. The council as good grounds for believing that the scheme will be adopted, and hopes that in the next eport it will be possible to speak of the actual stablishment of the institute.

Tuberculosis in Belfast.

It is only ten years since the Belfast Corporation ut into operation the existing scheme for the preven-on and treatment of tuberculosis, and the results chieved are noteworthy. The number of new cases xamined at the various centres during the year 1923 shows an increase of 227 on the previous year, this increase being probably attributable to greater care in notification. The death-rate in the city from pulmonary tuberculosis during 1923 has fallen for the fifth year in succession, and now stands at 1·3 per 1000, a reduction of 51 per cent. as compared with 1918, and of 72 per cent. as compared with 1890, when the death-rate was 4·7 per 1000. This affords some grounds for satisfaction, as the chief tuberculosis officer states in his annual report. A slight fall also occurred in the death-rate from the non-pulmonary forms of tuberculosis, which now stands at 0·3 per 1000, as compared with 0·36 in the previous year. The ratio of pulmonary tuberculosis to other forms of tuberculosis was 72 to 28. Of the 1151 patients found to be suffering from tuberculosis during the year 420, or over 36 per cent., had had personal association with tuberculosis amongst other members of their own families. In only 20 cases, or less than 5 per cent., was the relationship that of husband and wife. The report believes that "the most fruitful source of infection in children is probably through food and table utensils, and experiments have shown that not only tubercle bacilli but other infectious germs may be conveyed on the surface of tableware, such as cups, plates, knives, spoons, &c." The necessity for extreme cleanliness is emphasised. The nurses visited 902 homes with tuberculous patients. Of these 131 were reported as "good or very good," 567 as "average," 135 as "bad," and 69 as "very bad" or "exceptionally bad." On the whole, these figures suggest that the housing conditions in Belfast are relatively good compared with many other cities. Tenements hardly exist. The result of pregnancy in 1624 tuberculous mothers is recorded. Of these 129 miscarried, 1451 were delivered of a living child at full term, and 44 were delivered of a stillborn child at full term. Dental treatments were given to 1022 patients. An active educational propaganda was carried on during the year. The number of discharged soldiers treated during the year was 359. The open-air school for children living in contact with patients suffering from tuberculosis has been in successful operation, the number of children in attendance being 116.

A Charge of Bribery.

Last week Thomas Moran, a member of the dissolved Roscommon County Board of Health, was at Boyle remanded on bail on a charge of having solicited from Dr. McDonnell, a candidate for the position of medical officer of Kiltoom dispensary district, a bribe for his vote. Mr. Neilan, State solicitor, recalled that as a result of a complaint an inquiry was held by the Local Government Department. The election, in which Dr. McDonnell was defeated, was set aside and the Board of Health dissolved. Dr. McDonnell described how he met the accused in a hotel in Elphin, and asked him for his vote. "He replied," said witness, "he would be at a great loss if he voted for me; that there were between £400 and £500 being spent on the election, and that if I gave him that amount he could have me elected. He also said he would require £50 for his own vote, whether I won or lost."

THE "MILITARY SURGEON."—Col. J. R. Kean, of the United States Army, has been selected as the new editor of the *Military Surgeon.* On his retirement in June last, after 40 years service in the Medical Corps, he received a letter from the Acting Chief of Staff of the Corps Area, in which he was serving, expressing regret that he (Col. Kean) was retiring, and summing up his distinguished career, observing that he had been "a controlling influence wherever placed," that he had displayed signal abilities as chief surgeon of a corps in the war with Spain, that as chief sanitary officer in Cuba his service in the eradication of yellow fever had been of exceptional value, and that the Army Medical Department had gained repute owing to his advocacy of a Medical Reserve Corps (1908), and through his organisation of the American Red Cross base hospitals, and the U.S.A. Ambulance Service for duty with the French Army in the late war.

MOTOR CARS AND ACCESSORIES FOR 1925.

THE SHOW AT OLYMPIA.

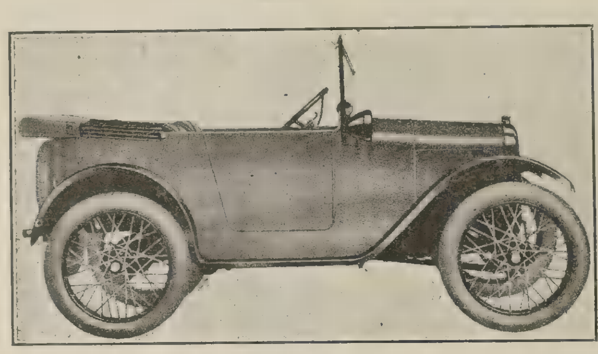
BY J. MARSHALL, M.I.A.E.,
LONDON MANAGER OF MESSRS. MANN, EGERTON AND CO., LTD.; OFFICIAL CONSULTING ENGINEER, MEDICAL INSURANCE AGENCY.

AMONG ardent motorists no political crisis can overshadow the importance of the Olympian motor show. It is likely to be as well attended as it was last year by eager amateurs. The best time to visit the show is quite early in the morning, between 10 and 12, and by those who can spare time on working days Saturdays should be avoided. The notes I have made on various types of cars which have proved popular in the past among medical men must be regarded merely as an indication of stands that should not be missed, certainly not as an exhaustive guide to a magnificent but somewhat unwieldy exhibition. Experienced motorists will know where to look for novelties and value; novices can only be urged not to buy blindly, but to reserve their choice if bewildered by the mass of good cars arranged for their inspection until they have sought the advice of an impartial expert. With these reservations I would suggest that visits be paid to the following stands.

Motor Cars.

Austin Motor Co. (Stand No. 141).—The Austin range of cars for 1925, at considerably reduced prices, comprise the well-known models of 20, 12, and 7 h.p., the principal alteration to the larger cars being the addition of four-wheel brakes and the introduction of a new 20 h.p. chassis with a very low frame, intended to facilitate entrance to closed bodies. This new frame is heavier than the old one and possesses a higher curve over the rear axle, where a larger spring deflection is given. Its advantages are particularly evident on the new "Carlton" saloon. A point of special interest on this and other bodies fitted on this chassis is the "all metal" framework which has been adopted in place of the usual wooden members; the body platform, stay supports, and, in fact, all parts generally made of wood are now being constructed of steel, which is claimed to provide a frame some 25 per cent. lighter than a wooden one. The 12 h.p. model is practically the same as last year, with the addition of four-wheel brakes. The four-wheel braking system adopted is a simple one, designed by the makers of the car; the front wheel brakes and their actuating mechanism are fitted as a complete unit, independent of the frame. The front brakes are compensated in relation to those at the rear; the compensation is located immediately beyond the pedal connexion and incorporates a hand adjustment, whilst the hand lever applies shoes to the drum mounted behind the gear box. The 7 h.p. Austin model has been improved in appearance, slightly enlarged, and modified in some minor respects (see Fig. 1). Recent success in the 200 miles race at Brooklands has proved that these little cars can stand a vast amount of hard work at high speeds. The following models can be seen on the stand: Touring car, £355, and "Windsor" saloon, £475, on 12 h.p. chassis; "Carlton" saloon, £675, and "Mayfair" saloon, £795, on 20 h.p. chassis Austin "Seven" touring, £155, and chassis, £120.

FIG. 1.



The "Austin seven" new model.

A.C. (Stand No. 18).—These cars are worth a visit; they are built on graceful lines, well proportioned, and the bodies are well constructed and extremely comfortable. The chassis is a creditable feat of engineering, and this make of car presents undoubted value at prices from £275 upwards. The engine (both four- and six-cylinder) is a sweet-running unit, and the braking power is unusually good; generally it will be found that the comfort of the owner-driver has been studied in many ways.

Standard Motor Co. (Stand No. 211).—As one of the oldest British makes these cars are always interesting, both for their attractive prices and bodywork designed to give roominess and comfort; designs show very slight modifications of last year's models. The 11 h.p. two- and four-seater at £235, the 11 h.p. "Weymann" saloon at £375, and the 14 h.p. saloon at £475 present excellent value.

Sunbeam Cars (Stand No. 98).—The prices of the 12/30, 14/40, and 20/60 h.p. (open car) remain unaltered. The enclosed types of the 20/60 h.p., however, have been increased slightly in price. Considering the quality of the product, the prices are not unduly high, since for reliability and general excellence of workmanship the Sunbeam models can scarcely be beaten. With the exception of the 12/30 h.p. all models are fitted with four-wheel brakes, and "Weymann" fabric bodies can be had for the 12/30 and 14/40 h.p. chassis.

Calthorpe Cars (Stand No. 86).—The 12/20 h.p. two- and four-seater, 12/20 h.p. saloon, and six-cylinder 14/45 h.p. models are being shown. These cars attract by reason of moderate prices and excellent coachwork. The saloon at £425 is worth close study, for it is roomy and well finished, and the 15/45 h.p. six-cylinder bristles with up-to-date ideas, while the touring model can be considered as giving excellent value at £395. The petrol consumption of the Calthorpes is extremely low, the 12/20 h.p. doing some 30 miles per gallon.

Bean Cars (Stand No. 89).—The exhibit comprises examples of the 12 and 14 h.p. The prices are practically the same as last year, but extra equipment is now included. The four-wheel brakes are of the "Perrot" type; balloon tyres and hydraulic shock absorbers on back and front axles are provided and on the touring models a windscreen for the rear seats. The prices are: 12 h.p. two-seater touring, £335; 12 h.p. four-seater touring, £345; 12 h.p. two-seater coupé, £395; 14 h.p. touring, £395; 14 h.p. saloon, £525. These cars are solidly built and the bodies are capacious. They will give continuous service over periods of prolonged hard work.

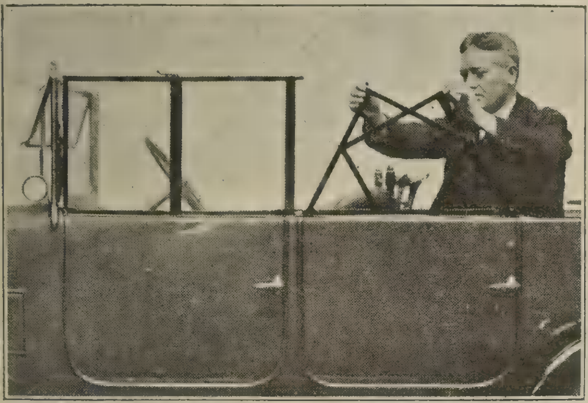
Fiat Motors (Stand No. 129).—These cars are essentially the same as last year. There are some minor modifications; for instance, the 10/15 h.p. has certain improvements to its electrical auxiliaries, and the longer chassis introduced last year has its steering column less raked, in order to give plenty of space for closed bodies. Prices are unaltered from those announced in August. These cars present remarkably good value.

Hillman Cars (Stand No. 167).—At £358 for the two-seater and £375 for the four- and five-seater, with patent all-weather bodies, Hillman cars show slightly increased prices, but with extra equipment and refinement they are well worth their present cost. The body has been widened considerably. 28-inch Dunlop cord balloon tyres and a comprehensive list of accessories are included.

Citroën Cars, Ltd. (Stand No. 23).—Notwithstanding the substantial decrease in price made a few months ago, further reductions have now taken place, and in addition numerous accessories are included. The Citroën, always reliable and reasonably priced, now gives wonderful value. The 7·5 h.p. with two-seater body costs only £145, the 11·4 h.p. English body four-seater £250, and the four-seater saloon £295. These are complete with balloon tyres, clock, speedometer, Boyce motometer, driving mirror, automatic windscreen wiper; and on the touring models folding rear windscreen. The French-built bodies are not very comfortable, the seats being too high in relation to the size of the body, but the English bodies are extremely well finished and will make a wide appeal.

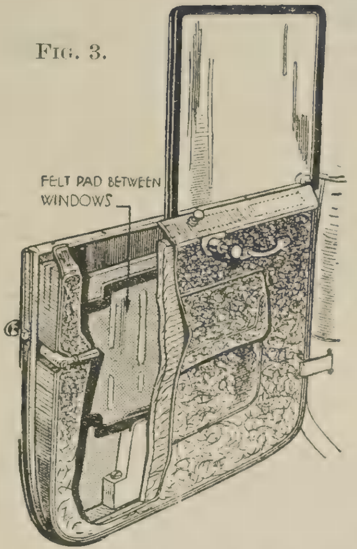
Humber, Ltd. (Stand No. 128).—Three models are now being marketed; the 8 h.p., the new 12 h.p., and the 15·9 h.p. These cars for a number of years have been noticeably well finished, and this year's models are up to standard. The new design of the all-weather side screens is probably unique; the screens can be screwed downwards and concealed in two or three sections in the curved side lines of the doors and body. The celluloid panels are fitted under compression in narrow metal frames to prevent buckling. These panels are formed over the doors and sides of the body in two halves, and when erect are kept together at the top by spring clips suitably held by a plated screw, so as to form a rigid structure. The method of storage and the appearance when up is clearly shown in Figs. 2 and 3. This system should solve many of the troubles now experienced in connexion with the ordinary type of all-weather fittings. The prices are: 8 h.p. from £240; 12 h.p. from £440; 15·9 h.p. from £630.

FIG. 2.



Method of raising and lowering side celluloid panels in Humber touring models.

FIG. 3.



Showing cavity in door where the Humber celluloid panels are housed when not in use.

Daimler Company (Stand No. 170).—What is termed by the makers "the largest car in the world" is shown—i.e., the 57 h.p. chassis, which was designed and built during the present year for the use of the King. One of the admirable qualities of this car is the very low entrance. The complete range of models shown is as follows: 16, 20, 25, 30, 35, 45, and 57 h.p., all of them with the Daimler six-cylinder sleeve valve engine, and worm and wheel back axle. In addition, the 10, 14, and 16 h.p. B.S.A. are on view. Much of the exceptional silence that characterises the running of these cars is due to a system of insulating the body from most of the shocks to which the chassis is subject. This is achieved by fitting an independent steel body frame which rests on rubber buffers situated on the top of the chassis. Moreover, the scuttle does not touch the bonnet in any way, so that complete insulation is ensured. Fabric panelled saloons are obtainable on the 35, 25, and 20 h.p. models for £250, and on the 16 h.p. for £160.

Vauxhall Motors, Ltd. (Stand No. 140).—The Vauxhall cars are always of distinguished appearance, and have established a sound reputation in many good road performances. The alterations from last year's types are slight; the 14/40, 23/60, and 30/98 h.p. models continue to be made. Some changes have been effected in the 14/40; a four-speed gear box, wire wheels, and Dunlop balloon tyres are now fitted. The 23/60 h.p. has four wheel brakes fitted as standard. These are of their well-known cable operated type.

Rover Co., Ltd. (Stand No. 173).—This firm have brought out a new 13·9 h.p. two-litre chassis which has many original and up-to-date features. It is capable, in full touring trim, of a maximum speed of 60 miles per hour. At first sight the chassis may seem somewhat heavy and complicated, but in view of the accessibility of the parts this can readily be forgiven. Of the other models, the 8 h.p. two-cylinder air-cooled type is being retained, and also the new 9 h.p. four-cylinder overhead valve. The four-seater body of the last-named car has only one wide door; this gives particularly easy access to the rear seats as the front near-side cushion is hinged forward, and the separate back is swung round so as to rest at right angles to the back of the driver's seat.

De Dion Bouton Cars (Stand No. 212).—The manufacturers are showing various types of their 12/28 and 15/43 h.p. cars. They are among the oldest and most reliable French car-makers, and the De Dion Bouton chassis has always had a good name. A delightfully finished 2/4 seater coupé body is shown here called the "Sportsman." It is very roomy, is fitted with two adjustable front seats, two sliding occasional seats, wide doors, and accommodation is provided for carrying luggage, golf clubs, &c., the cost of this body on a 12/28 h.p. chassis being £695. The prices quoted are, perhaps, a little on the high side by comparison with other well-constructed chassis, but for those who are prepared to pay for the undoubted security of good workmanship embodied in these cars I can cordially recommend them.

Cubitt Engineering Co. (Stand No. 19).—This firm concentrates on one type only—namely, the 15·9 h.p. (tax £16). The production is of particularly robust nature and has an unusually roomy body. By standardisation of one type, the makers have been able to reduce their prices on every model by £60 per car. At the present price the car appears a good proposition.

General Motors, Ltd., *Buick* (Stand No. 138).—These are among the most reliable and popular types of

American- and Canadian-built cars. They are conspicuous for smooth running and large comfortable bodies. The new 20 h.p. 6-cylinder is an exact replica on a small scale of the "Big Six," which has been running successfully for some years, and it may be relied on to show the Buick qualities of power and dependability. At £395 for the tourer and £525 for a saloon it can be considered cheap.

Unic (Stand No. 178).—These cars are always worth inspection; the 12/23 h.p. French saloon at £495 and the English saloon, or landaulette, at £550, are, perhaps, rather too highly priced. The chassis is, however, reliable, and once the initial cost is over the owners of Unics are, as a rule, well satisfied with their choice.

Leyland Motors (Stand No. 219).—The Trojan shown on this stand will attract attention by its unconventional appearance and design. The principle on which this car is built is peculiar to itself, and has proved quite satisfactory during 18 months' trial under strenuous conditions to many owners, including a large number of doctors. The Trojan has solid tyres, compensated for by special springs and a two-stroke engine which possesses extraordinary pulling powers.

Morris Motors (Stand No. 210).—A crowd will doubtless be attracted to the stand where the wonderful value given in all models made by this firm is demonstrated. These cars are all strong and reliable, and it is only by production on a huge scale that they can be sold at such low prices. Morris cars are a striking example of cars of excellent quality produced en masse, and therefore at low price, by an enterprising firm. They are deservedly popular among medical men. The new reduced prices enable a two-seater Morris-Cowley to be purchased for £175, whereas the most expensive body—the saloon—on a Morris-Oxford chassis can be acquired for £385, including front wheel brakes. Between these two figures any type of car can be purchased and a full insurance (general accident policy) for a year is given in addition to all desirable accessories.

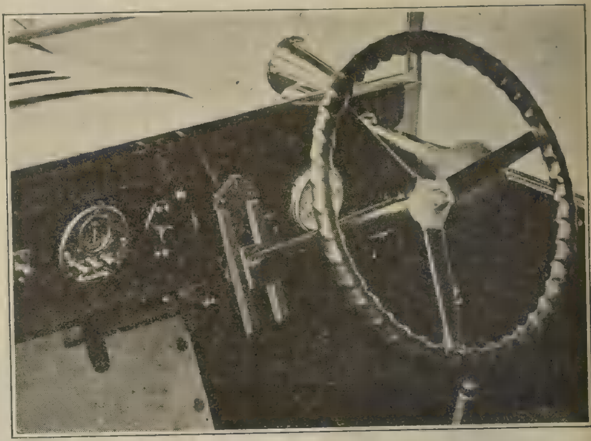
Wolseley Motors (Stand No. 168).—Examples are shown of the 11/22 (late 10 h.p.), the 16/35 (late 14 h.p.), and 24/55 (late 20 h.p.). Prices are slightly reduced from last year, and in addition there is an exceedingly generous accessory equipment. The chassis exhibited vary only slightly in detail from those shown last year. The Wolseley 20 is an excellent proposition.

G.W.K. Cars (Stand No. 37).—To the medical profession this car must prove of interest, as they are asked from time to time whether it is possible, or safe, for more or less disabled persons to drive. In this car, specially constructed for the disabled, there is no gear-box, and the speed is varied by the movement of a disc composed of two outer rings of fibre and a centre ring of cork, all three being clamped together in the usual manner, with side-plates and bolts, and at right-angles across the face of another disc. In the model exhibited pedals are absent, both clutch and foot-brake being operated by pulling the steering column downwards (see Fig. 4). Prices vary from £200 for the two-seater, to £225 for the four-seater. Details of the mechanism of this car were given in THE LANCET last April,[1] and I may venture to emphasise the valuable advice then given that a disabled individual should, in his own interests, submit to one of the standard driving tests before taking the road.

Coachwork.

Many new ideas for finishing coachwork in place of painting are now coming on the market, and a remarkably successful finish is achieved by the use of "Carmaloid" made and developed by R. I. Clark and Co., West Ham Abbey, London, E. 15. This substance is a celluloid enamel which is applied simply by pouring the material over the panels out of a spout. The coats dry quickly at normal temperature; after about 20 minutes the enamel is impervious to dust. A body finished with this preparation need never be washed, but merely rubbed with a leather. The friction of dust merely serves as a polish, since the surface is too hard to be scratched. Tar, the removal of which ruins a varnished surface, can be dissolved by a cloth soaked in petrol or benzol, because the celluloid finish is impervious to either of these tar solvents. To the medical man, whose car is almost constantly on the road, this system should make a special appeal when the need for repainting arises.[2]

FIG. 4.

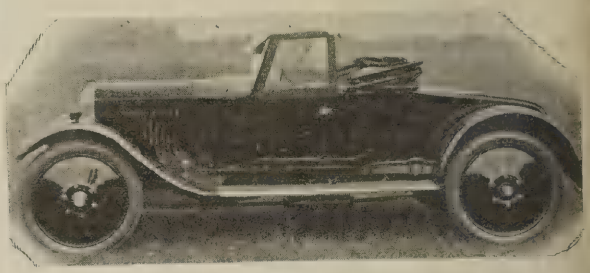


Control apparatus of G.W.K. cars fitted for disabled drivers. Note the absence of pedals, and the guide for the upward and downward movement of the steering column, which operates clutch and brake.

Offords (Stand No. 122 Coach-building Annexe).—An example of this firm's work will be seen on an 18 Armstrong-Siddeley chassis, consisting of a Coupé de Ville Landaulette. The workmanship and general finish will be found good and the price reasonable.

Mann, Egerton and Co., Ltd. (Stand No. 202 Coach-building Annexe).—A special doctor's two-seater body fitted to a 14 h.p. Vauxhall chassis is being shown. This body incorporates many features suggested by members of the medical profession, including two doors made specially wide for easy entrance and an all-metal sloping windscreen, constructed with the lower edge of the top glass panel shaped to drain water to the outside edges. The price has been kept down to £625, complete with full equipment. (See Fig. 5.)

FIG. 5.



Special doctor's 2-seater semi-coupé (Vauxhall and Mann Egerton).

Accessories.

Petrol.—All the well-known firms have stands. I am often asked as to whether there is any disadvantage in mixing petrol of different makes. In practice so long as No. 1 quality is used it does not seem to make much difference whether B.P., Shell, Pratt, or any other reliable makes are used together when this happens to be convenient, or the owner's favourite brand is not available.

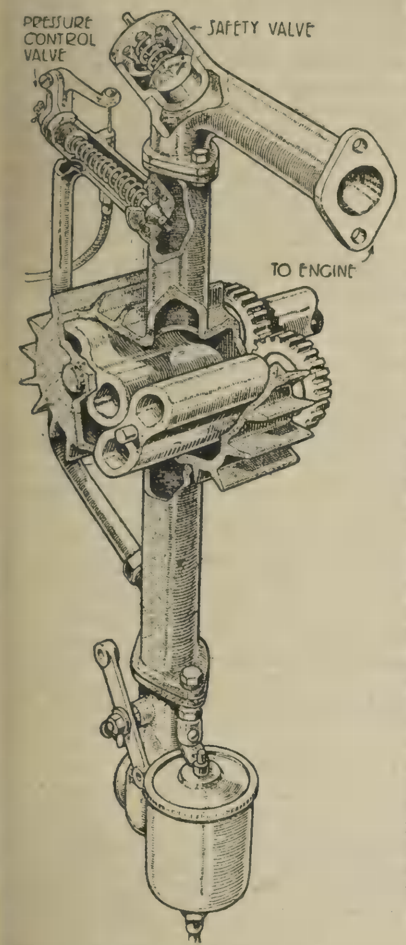
---

[1] 1924, i., 885.

[2] I am informed that, while no examples of this finish are on show at Olympia, demonstrations of the process will be given to any medical men by Messrs. Clark and Co. at their works.

Superchargers.—The average motorist has not hitherto been much interested in superchargers, but these devices for increasing horse-power are likely to be applied to ordinary private cars in the near future. Under present conditions cylinders are not filled with gas at fairly high speeds, nor is the spent exhaust gas entirely exhausted; thus every new charge in the cylinder is unsatisfactory as to quality, and is, moreover, diluted by undischarged exhaust-gas. A supercharger completely fills the cylinders of the engine with gas at high engine speeds with the consequent gain of much extra power. Without going too closely into technical details, supercharging involves the use of a blower (see Fig. 6) between the carburettor and the engine. This runs practically at crankshaft speed and increases the horse-power enormously. If the present method of taxation remains in use, no doubt some relief will be sought with a device of this description, for it will enable us to use smaller engines for the taxable horse-power.

FIG. 6.

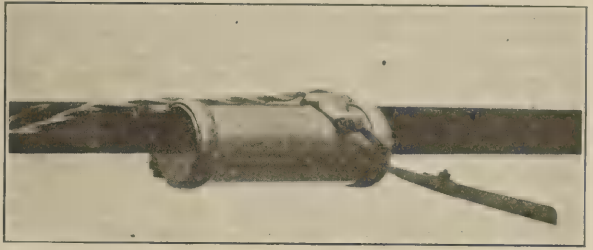


Diagrammatic view of the lay-out of an induction system incorporating a Roots blower.

Lifting Jacks.—Now that so many cars are fitted with balloon tyres it is obvious—owing to the great difference in height of the axle when the tyre is flat and when pumped up to the required pressure—that the old type of lifting jack is useless, and the buyer should therefore see that some form of double lifting jack is supplied with the equipment. There is a convenient type of jack, called the "Stevenson," which comprises two jacks permanently fitted to the chassis, one on either side, thus enabling both wheels to be lifted on either side of the car by the simple operation of turning a handle. This handle is detachable and it is only necessary to push it on to a square shaft, which is flush on the running board and protected by a rubber cap. The price of this jack system is only £6 6*s.* complete. It can be seen on the Darracq stand (No. 126).

Dunlop Rubber Co. (Stand No. 500, Gallery, Main Hall).—The bulk of our British cars are now fitted with Dunlop tyres as standard equipment. I believe this make to be one of the best at present being manufactured and the new balloon type is worth careful examination. Full information as to cost of conversion from ordinary to balloon equipment will be given by the company on application. They have issued an excellent inexpensive guide at 5*s.* It includes good, legible, and easily followed road maps, and full details of hotels and garage prices in most towns of reasonable size. A section at the end of the volume is devoted to lighting-up tables, index marks, ferries, and a short summary of the simpler side of motor-car law.

FIG. 7.

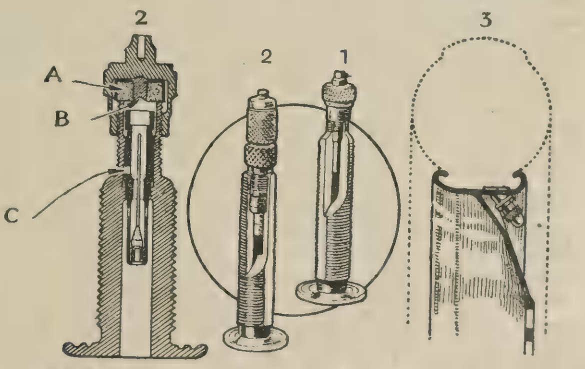


A new type of windscreen wiper working on the "solenoid" system. (Fluid Pressure Pumps, Ltd.)

Lodge Sparking Plugs (Stand No. 426) are worth examination by those unfamiliar with their robust construction. In practice they are reliable and give long service.

A new electrically driven *Windscreen Wiper*, ingenious and efficient, has been produced by Fluid Pressure Pumps, Ltd. (Stand No. 370). It is actuated on the well-known "solenoid" principle, and made in two types, both quite silent in operation. One type is actuated by a small switch which clips on to the rim of the steering wheel. Pressure on the switch button causes the squeegee to make a semicircular sweep and return automatically to the horizontal position. The second type is rather more elaborate and can be made to operate automatically at fixed intervals adjustable from 10 to 30 seconds. The first type is 22*s.* 6*d.*, and the other 32*s.* 6*d.* (see Fig. 7). An advantage of the "solenoid" system is that the current required to operate is practically negligible.

FIG. 8.

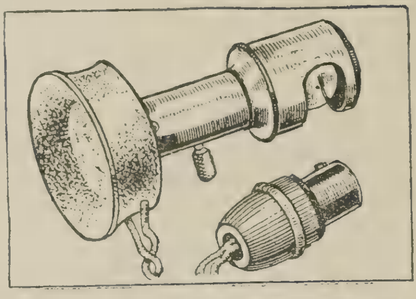


A new Michelin tyre valve. 1. Old type of valve. 2. New type of valve. 3. Shows position of valve in new steel disc wheel. A, Rubber enclosed in metal cap. B, Metal centre which takes top of plunger stem and pushes it down. C, Vent allowing air to escape when deflating tyre.

Michelin Tyre Co. (Stand No. 519).—After using the same type of tyre valve for more than 20 years, the Michelin Co. have produced and standardised a new valve, the special design of cap employed being alone responsible for retaining the air in the tube. The old rubber-headed plunger is still used, but it operates only when the tyre is being inflated. Fig. 8 shows the difference between the old (1) and new (2) type, whilst (3) gives the position of the valve in the steel disc wheel. Briefly, the valve cap contains a rubber plug enclosed in a small metal cup, and has a metal centre with a small depression in it to take the top of the plunger stem. When the tyre is fully inflated the valve cap is screwed on and the plunger, being pushed downwards to its seating, falls to the bottom of its working chamber. This type obviates many of the troubles inseparable from the older valve, such as leakage due to grit or dirt on the plunger seating or the perishing of washers. In the new type the valve cap does the bulk of the work, obviously a more satisfactory arrangement.

Guiterman and Co. (Stand No. 284) show an interesting inspection lamp. This is fitted with a suction cup at one end and can thus be stuck on to any convenient part of the car, leaving both hands free to work (Fig. 9).

Fig. 9.



Guiterman's suction cup inspection lamp.

General Notes.

The following points serve as a useful guide to present practice in chassis design: (1) Four-cylinder engines form about 75 per cent. of the total. (2) About 10 per cent. more cars are fitted with four speeds than with 3 speeds. (3) Pump and thermo-syphon system cooling are about equally popular. (4) Centre and side control are used in about equal proportions, and it should be noted that either can be operated with facility. Central changing is a little awkward perhaps, particularly on a two-seater, owing to its being practically impossible to seat three persons abreast; moreover, two rugs must be used in cold weather. On the other hand, it makes for easy entrance from doors on either side; whereas the side control is obstructive unless the body is built with wide doors. On the whole, therefore, it might seem that for the medical man central control on small or medium powered cars is the most advantageous. (5) Magneto ignition is used on 75 per cent. of the total number of cars shown. (6) As to brakes, ordinary two-wheel and four-wheel are about equally divided.

There is a tendency for *chassis frames* to be lower than heretofore, this policy being, I consider, in the right direction; it enables the coachbuilders to produce a body much nearer the ground, thus reducing wind resistance and roll on corners, and giving a lower entrance step for passengers.

Some indication is noticed towards *six-cylinder cars* with a small horse power. Doubtless in time these will become more universal, but progress is slow, the average user being a little nervous of what he thinks is the added complication of two extra cylinders.

It is noticeable that in many cars the framework of covered bodies is built of metal in place of wood, door pillars included, a light framework of wood being attached to the metal work for upholstery to be fixed to. This idea presents an interesting problem and may very likely lead to further developments in this direction owing to its strength and lightness.

Balloon Tyres and Springing.—Since most medium and smaller powered cars are now fitted with the balloon or low pressure tyre, the question of springing should be gone into carefully by the would-be purchaser. It must be remembered that to obtain the full benefit of balloon tyre comfort some form of rebound snubber or shock absorber should be fitted, particularly on the four-seater cars, for whilst absorbing the small shocks due to rough stretches of roads, these tyres, owing to their great flexibility, tend to create an excessive "up throw" of the body and springs. The cost of absorbers or snubbers varies from £5 5s. upwards according to the size of the car.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are notified: Surg. Comdrs,: A. E. Malone to *Capetown*, on recommg.; and H. A. Kellond-Knight to *Hecla*.

Surg. Lt.-Comdrs.: R. Buddle to *Vivid*, addl., for R.N. Hospl., Plymouth, as Instructor to Sick Berth Staff; N. A. H. Barlow to *Victory*, addl., for R.M. Infirmary, Eastney; and O. D. Brownfield to *Bryony*.

Surg.-Lt. D. M. Beaton to *Royal Oak*.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. E. E. Parkes is placed on the half-pay list on account of ill-health.

TERRITORIAL ARMY.

The undermentioned Lt.-Cols. to be Bt. Cols.: C. R. White, F. Whalley, C. L. Isaac, J. W. Keay, F. Darlow, R. E. Bickerton, T. B. Wolstenholme, and G. L. Thornton.

Lt.-Col. C. W. Ponder to be Bt. Col.

Maj. R. M. Wilson having attained the age limit is retd. and retains his rank.

Maj. (Prov.) O. Teichman is confirmed in his rank.

Maj. L. Ball resigns his commn. and retains the rank of Maj.

Capt. A. F. Wright (late R.A.M.C.) to be Capt.

TERRITORIAL ARMY RESERVE.

Lt.-Col. F. Hawthorn to be Bt. Col.

ROYAL AIR FORCE.

D. Magrath is granted a short service commission as a Flying Officer.

Flight Lts. R. G. J. McCullagh and C. Y. Roberts are transferred to the Reserve, Class D.2.

INDIAN MEDICAL SERVICE.

Maj. A. E. Meredith and Capt. W. E. Maxwell are confirmed in their rank.

Lt. F. H. Whyte (Prov.) to be Capt.

The King has approved the restoration to the active list from the temp. non-effective list of Maj. Abdus Sattar Khan.

The King has approved of the retirement of Lt.-Cols. W. G. Liston and J. W. Grant.

DEATHS IN THE SERVICES.

Major-General Sir Robert S. Findlay Henderson, K.C.M.G., C.B., retired Surgeon-General A.M.S., died on Oct. 5th, at the Queen Alexandra Military Hospital, at the age of 65. The son of the Rev. R. Henderson, senior chaplain, Bengal, he received his medical training at St. Mary's Hospital and at Edinburgh University, where he graduated in medicine and surgery in 1882. Two years later he entered the Army Medical Service and served in the Sudan campaign of 1885. He also served in the Burmese expedition of 1885–87, in Upper Burma against the Katchens, 1887–89, and in the Chin Lushai expedition of 1890. He was P.M.O. of the Wuntho expedition of 1891 and was mentioned in despatches, and served with the Malakand Field Force in 1897. For services in the South African war, where he was in command of field hospitals, he received the Queen's Medal, and in 1907 he was appointed secretary to Netley Hospital, becoming secretary to the Director of Medical Services in India a year later, a position which he held for four years. In 1914 he was appointed Assistant Director of Medical Services in the Quetta Division and later to the 17th Division, subsequently becoming Director-General of the New Zealand Medical Services. Sir Robert Henderson, who was an honorary physician to the King, retired in 1917 with the honorary rank of major-general, and received in the same year the C.B. He received the K.C.M.G. in 1919.

Correspondence.

"Audi alteram partem."

IS SANATORIUM TREATMENT ECONOMICALLY SOUND ?

To the Editor of THE LANCET.

SIR,—The question, Are we sure that sanatorium treatment is economically sound ? asked by "Medicus" in your issue of Oct. 4th, cannot be answered categorically. It is impossible to weigh against each other with the exactness of a laboratory experiment the results attained by two different methods of treatment. Papers published in 1921 by E. Ward[1] and n 1922 by G. Lissant Cox[2] reach different conclusions as to the relative values of sanatorium and domiciliary reatment in cases of pulmonary tuberculosis. The difficulty is to get really comparable cases, since it is nconceivable that the cases which receive sanatorium reatment are of the same class as those who refuse or are refused sanatorium treatment. Hence, until some public authority has the courage to treat a large series of cases by the two methods, assigning them alternately to one or other as they come, we shall have to depend for a judgment on less conclusive evidence.

There is ample evidence that many slight cases of uberculosis recover without treatment and without being diagnosed, but tuberculosis is a serious disease when its symptoms really obtrude themselves and render the patient unfit for his work. In this stage the following conditions are generally essential for uccessful treatment: (*a*) Skilled medical control, which includes nursing; (*b*) good material conditions n respect of accommodation and food; (*c*) an tmosphere or environment which favourably affects he patient's psychology; and (*d*) the coöperation of he patient himself. If all these were present in the ome treatment of tuberculosis, the results would, oubtless, be little different from those obtained in anatoria. But are they ? While it is true that the deas underlying sanatorium treatment have to some xtent permeated general medicine, and are appreiated by the public and by the press to a much reater extent than they were even ten years ago, et it is no disrespect to our professional brethren ngaged in general practice to say that there are very w of them who have more than a nodding acquainance with the principles of the hygienic-dietetic reatment as carried out in the ordinary well-run anatorium. The exceptions are, in most cases, ormer patients or former medical officers of sanatoria. real knowledge of the behaviour of the body emperature in tuberculosis and of the influence of xercise on the course of the disease is seldom acquired n the medical schools or, indeed, outside the anatorium.

It is readily admitted that in the past men have not frequently been appointed to take charge of sanatoria tuberculosis dispensaries who had no special nowledge of tuberculosis, and that even now one or wo county councils believe they can get efficient spensary service from officers who do also routine edical inspection of school-children and function as perts in infant welfare, and possibly also in venereal seases and general public health. But in these days uch lapses are very rare, and there are very few cases here the sanatorium superintendent or the tuberulosis officer cannot be ranked as a specialist in his bject.

Again, it is seldom that a working-class patient can cure at home the accommodation and the food hich he ought to have. While exposing his family to tra risk of infection, he diminishes their resistance requiring a share of their food. As important as y factor for his speedy recovery is the environment. his own home the patient is regarded by himself nd by others as a diseased person among healthy persons, constantly reminded of his affliction, requiring special consideration and subject to all the anxieties and annoyances of a household struggling along with diminished resources. In the sanatorium, on the other hand, he enters a new atmosphere where all are in the same boat as himself, and where everything is specifically directed, and not improvised, for the treatment of his ailment. His domestic troubles are dimmed by the want of contact with them, his mind is kept occupied by a well-ordered routine with things other than his own ill-health and his family worries. Sanatorium patients do often worry about their financial and family affairs, but nevertheless make progress towards recovery, and would in all probability worry considerably more if they were actually living at home. It is true that there are a few cases who feel the separation from their families so keenly, or are from their temperament so miserable in the sanatorium, that they may make a better recovery at home. Such cases are undoubtedly exceptional. Ordinarily the sanatorium patient is more cheerful, and is animated with a better hope of recovery than the patient treated at home. This may not be true in those institutions where advanced and even dying cases are treated alongside curable cases. The spirit of hope that is so important for the recovery of the latter is transferred to the former, for whom it can avail nothing except to add temporarily to their peace of mind. Medical officers of health lay considerable stress on the educational value of sanatorium treatment, as an asset in protecting the rest of the community, even if it did nothing to help the patient. Thus the sanatorium does considerably more than work for the individual.

It is sometimes argued that the money spent on the institutional treatment of pulmonary cases could be used to much better advantage in raising the standard of living of the patient and his family while his ill-health is being treated in his own home. If we assume, as is reasonable, that each case receives an average of four months of sanatorium treatment costing £3 a week, the cost is approximately £50. How far will such a sum, added to other assistance which he might in any case receive from public funds after leaving the sanatorium, go in providing maintenance or extra nourishment, better housing conditions, medical attendance, and drugs for a person whose incapacity for work is likely to last for at least a year, and whose partial disability ending either in recovery or in death has been estimated to last on the average over three years from the time of first requiring treatment ? I am, Sir, yours faithfully,

JAMES WATT.

King George V. Sanatorium, Godalming, Surrey,

ANTIMONY TARTRATE IN BILHARZIA.

To the Editor of THE LANCET.

SIR,—Judging from the published reports of those who have used the sodium salt of antimony tartrate in the treatment of bilharzia disease in Africa, it is necessary to use from 25 to 30 gr. to effect a permanent cure. By using the potassium salt, I have found that a cure can be effected in the vast majority of cases in Natal by using half this total dose. Further than that, I have shown that, where the drug is dissolved in not more than 3 c.cm. of boiling saline and doses of gr. ½ to 1½ are employed for a juvenile adult, a cure is obtained practically without toxic effect throughout the series of injections. Where there is extensive destruction of the liver substance, as is so common in patients infected with *Schistosoma japonicum* and is occasionally met with in the African varieties of bilharzia disease, it is most desirable that the smallest possible total dose of antimony should be employed and distilled water avoided; for this reason, I consider that the substitution of the sodium for the potassium salt as originally used at Khartoum by Dr. J. B. Christopherson is unwarranted, and would strongly urge upon those practitioners who are called upon to treat schistosomiasis in its various forms with antimony to confine themselves to the use of the potassium salt dissolved in saline.

FACT AND THEORY IN RADIO-THERAPY.

To the Editor of THE LANCET.

SIR,—Prof. Russ takes me to task for certain statements in my article on Some Principles of Treatment in the Radio-therapeutics of Cancer (THE LANCET, Sept. 27th).

1. Referring to a former denial on my part that ultra-violet rays could benefit deep-seated diseases, "because they had practically no penetration," I quoted instances to show that such benefit was now clinically proved, and added that "we should beware of denying clinical facts because of physical theories." Prof. Russ says: "I do not think we should blame theory here; *judgment upon the physical facts has been wrong* (italics mine), but even the facts were right." This statement appears to me somewhat lacking in lucidity, but I take it to mean that the absence of power on the part of ultra-violet rays to penetrate the body tissues remains undisputed. Quite so. It is the "judgment upon the physical facts" which has been wrong. Now, it may be due to my lack of clear thinking if "judgment upon physical facts" appears to be own brother to a "physical theory"; but so it seems to me. A theory is the outcome of reasoning, and in the case of exophthalmic goitre the syllogism was as follows: (*a*) Unless a radiation penetrates the skin it can have no effect on underlying organs; (*b*) ultra-violet rays cannot penetrate the skin—the thyroid is covered by the skin; (*c*) therefore ultra-violet rays cannot affect this organ. The major premiss was at fault, because it rested on physics without physiology. It was a flagrant example of the denial of clinical fact because of physical theory. I singled it out, because I had myself been guilty, but, unfortunately, medical history abounds with such examples.

2. I am accused of opposing a theory to a fact in the matter of acquired immunity on the part of tumours against X rays. Prof. Russ says: "He is discussing the well-known clinical fact that growths become apparently resistant to repeated application of X rays. Obviously, this may be due either to the malignant cells or to the tissues of the host, an alternative not easily decided upon in the human body. *He then refers to the fact that when animal tumours are removed from the body, and given repeated doses of X rays, the same phenomenon appears*" (italics mine). Now, while I was quite familiar with Prof. Russ's work on these lines (*Brit. Jour. Radiology*, August, 1924), I purposely avoided discussing it in my paper for the very reason that it was concerned with dosage outside the body, a procedure which has no clinical analogue. If Prof. Russ can show me the reference italicised either on page 638 or elsewhere in my paper I shall be greatly surprised. I think his enthusiasm has led him to assume some such reference must be there! I confined myself—or believe I confined myself—to clinical considerations alone. I do not for a moment deny the possibility that acquired immunity may be transmitted; but the view that, in the human subject, favourable mutations among the cancer cells may play a part is not without supporting evidence. For it is well known that when the remains of irradiated growths are examined microscopically, intact cancer cells are often found here and there amongst the corpus of their companions. The precise nature of the immunity was not, however, of importance to my argument, as I was rather concerned to show that a general failure of body resistance was of more importance in determining the final break-up than any acquired immunity on the part of the original tumour mass.

3. On page 635 I say: "The wave-length most suitable for any given type of growth must be found by clinical observation, and cannot be deduced a priori from any physical considerations." This statement was made in connexion with the warning not to pit physical theories against clinical facts, and was not intended to refer to laboratory experiments upon living animals. I follow such experiments with the greatest possible interest, and look to them to furnish new ideas which may be tried out on actual patients. If Prof. Russ will look through my writings for the past ten years, he will find very few of them (not excepting this latest paper) in which his work is not referred to, and always with appreciation.

But, when all this is admitted, one cannot "lift" the results obtained for experiments on animals and apply them forthwith to the human subject. Many disappointments have come from the attempt. And if this is true for experimental work done in the body, how much more is it true with regard to work done out of the body! The final experiment must always be clinical—i.e., upon the body of a human being.

I am, Sir, yours faithfully,
F. HERNAMAN-JOHNSON.

Harley-street, W., Oct. 11th, 1924.

DENTAL DRESSERS.

To the Editor of THE LANCET.

SIR,—I find it difficult to follow the arguments of Dr. Barwise which would make it appear that "Codlin's the friend, not Short," and that under a curious disguise he is only the true friend of the dental profession. I for one find myself lacking in a proper sense of gratitude. The real issue is not the efficiency of the dental dressers employed by the Derbyshire County Council, but whether unqualified and partly-trained individuals should be allowed to perform any operations in the mouth. The examining bodies demand a course of not less than four years training at a general and dental hospital for a dental student. The examinations are not easy and cover a wide field. If such strenuous training is considered necessary before a dentist is allowed to practise, it seems to me that the relatively slight training proposed by Dr. Barwise is not sufficient to allow such individuals to carry out dental treatment skilfully and efficiently. The Dental Board regards a proper training as so essential that if any dentist allowed a dental dresser to carry out operations of the nature advocated by Dr. Barwise, in his own practice, he would undoubtedly be regarded as committing the offence of "covering" and would be liable to have his name erased from the Dental Register. Dr. Barwise's attitude is strongly reminiscent of the newly-qualified doctor who knew enough to treat children!

Dr. Barwise complains that I have not inspected the work done by his dental dressers, but I am not debarred from criticising his proposals, for the principle involved is of great importance and far transcends the question of how these particular individuals perform their work. My experience as a dental surgeon both to a dental hospital and a children's hospital has convinced me that the dental treatment of children is the most difficult work which a dentist has to perform. The newly-qualified dentist is but a tyro in this branch of dentistry. How much less efficient those whose training is of the limited characte suggested by Dr. Barwise. What would the attitud of the medical profession be toward a proposal tha minor medical work should be carried out by partly trained individuals? I am certain that doctors woul oppose any such proposal, even to cope with condition for which the number of qualified practitioners wa insufficient. It would be rightly said that there is n minor medicine which is always minor and therefor within the competence of an unqualified person At any time some unexpected difficulty may aris calling for the highest skill of the medical man. Th same argument applies to dental operations by partly trained dressers and it is for this reason that I am opposed to Dr. Barwise's proposals.

With regard to the contention that the number o dentists is insufficient for the work, a primary argu ment for the employment of dental dressers, this cannot possibly be sustained. For a recent appointment as full-time dentist at Dewsbury there were 73 applicants. This is not exceptional and disposes effectively of the statement that there is a shortage of dentists. I am Sir, yours faithfully,

Wimpole-street, W., Oct. 11th, 1924. A. T. PITTS.

REPRESSION OF PAINFUL MEMORIES.

To the Editor of THE LANCET.

SIR,—Dr. Hugh Wingfield's letter, published in THE LANCET of Oct. 4th, gives an interesting account of the origin of repressed memories with which I am in the main in agreement. But the process of forgetting would seem to be Nature's remedy for painful experiences, and the majority of repressed memories of childhood surely remain harmless. Nearly every child, I suppose, has been smacked at some time and forgotten the smacking which leads to no bad after-effects.

What is it, then, that produces the pathological repressed memory which in after life gives rise to the distressing symptoms we find so often in our nervous patients? I have found in nearly every case that the emotional disturbance is out of all proportion to the physical injury which generally has occurred. A sense of injustice is often an important symptom, followed, it may be, by a desire for revenge or protection against a similar experience in the future; this n turn leads to obsessional acts which the patient s quite unable to explain. When the memory is revived by hypnotism the acts and emotions are explained correctly by the patient to himself and the adult power of reasoning takes command; the cause of the distressing emotions is understood, and his, I believe, to be the reason why the recovery of he repressed memory cures the symptoms. In future, should anything occur to recall his former experience the emotion will still arise, but with it the memory and the explanation which will in turn subside, until in most cases the symptoms are no longer evident, or are so slight that they can be controlled.

I do not agree that "recalled painful memories do us no harm." They do not, of course, produce the distressful symptoms of a repressed memory, but which of us can say that memories of the late war do not affect us adversely? So much so that most people are trying to forget it. In dealing with patients, too, the physician has to tread delicately, for although in the revival of repressed memories by hypnotism or other means we possess a very valuable form of treatment which performs an undoubted cure in certain cases, it is well to remember, as Freud says n his Introductory Lectures on Psycho-Analysis, translated by Mrs. Riviere (page 320): "Although it may be said of every neurotic that he has taken flight into illness,' it must be admitted that in many cases this flight is fully justified, and the physician who has perceived this state of things will silently and considerately retire."

I am, Sir, yours faithfully,
PERCIVAL S. CONNELLAN.
Bloomsbury Dispensary, W.C., Oct. 6th, 1924.

GAS-AND-OXYGEN ANÆSTHESIA IN ILL PATIENTS.

To the Editor of THE LANCET.

SIR,—Dr. W. B. Howell's article in your issue of Oct. 11th is valuable to anæsthetists not only because t confirms our present knowledge of the power of adrenalin to restore the heart-beat, and of the echnique of its injection, but also because it draws attention in a vivid manner to the difficulties and danger of nitrous oxide and oxygen in anæsthetising patients who are seriously ill. It may even strengthen he conviction of some that nitrous oxide and oxygen, although in theory the ideal anæsthetic for the hocked, the exhausted, and the toxæmic patient, is often the most dangerous of all general anæsthetics in actual practice.

The reasons for this conviction are not far to seek: they may be briefly stated by saying that nitrous oxide and oxygen produces indifferent muscular relaxation in the presence of sufficient oxygen to maintain complete oxygenation of the blood and that, in consequence, anæsthesia with this agent is nearly always accompanied by a slight degree of anoxæmia; more particularly if the abdomen is the seat of operation, or an operation is being performed which demands a quiet and fairly well-relaxed subject. I feel almost inclined, from experience and observation, to go even further and to say that I do not believe that anæsthesia can be obtained and maintained with this anæsthetic in the human subject without a slight degree of shortage of oxygen, judging not by the colour of the face but by the colour of the blood in the wound. However this may be, it is certain that the heart and central nervous system of a healthy patient can withstand this handicap for a considerable time, but that a long-continued anoxæmia, even if of slight degree, may prove too much for a very ill patient, or a patient who is disabled by a cardio-vascular, bronchial, or pulmonary lesion. It is wiser to add a little ether, which by deepening anæsthesia allows the use of an excess of oxygen, or to employ local anæsthesia in conjunction with nitrous oxide and oxygen, than to supplement the action of this gas by anoxæmia.

Prolonged nitrous oxide-oxygen anæsthesia suffers from another disadvantage in cases of active pulmonary tuberculosis. Rest in the recumbent posture is still part of the accepted treatment of this stage of the disease, and the resumption of physical activity is slow and gradual. If this state of rest is contrasted with the state of increased pulmonary ventilation, which exists during this anæsthesia, the question at once arises whether some other method of anæsthesia, local or general, is not advisable. Spinal analgesia is indicated in some of these cases, and in others I believe that ethylene, judging by the experience of the Mayo Clinic (*Brit. Jour. of Anæsth.*, II., i., 13) and a limited trial of this gas at Guy's, will be found to offer a solution of the problem.

Dr. Howell notes the "long period of unconsciousness" after resuscitation of the heart and quotes the unique case reported by Mr. Mollison. It is important to put on record the fact, which Mr. Mollison very kindly authorises me to use, that the mental development of this boy was very backward for at least two years afterwards. It is another proof of the grave damage which is done to the nervous system by diminishing or cutting off its supply of oxygen.

I am, Sir, yours faithfully,
Regent's Park, Oct. 11th. FRANCIS E. SHIPWAY.

FUR DERMATITIS.

To the Editor of THE LANCET.

SIR,—In a recent issue (THE LANCET, Sept. 6th, p. 505) attention was called to the report on this subject issued by the Ministry of Health. From the pathological and social points of view this report seems to me to require further comment. While describing various products of para- and metaphenylendiamin, to which the symptoms have been attributed, it omits reference to the important point that it is not a difficult procedure actually to test either a fur or a chemical product in order to decide whether it is or is not, in fact, irritating to human skin. I have already described (*Medical Press and Circular*, March 26th, 1924) the procedure and the results which may be obtained. As the report of the Ministry stands, no evidence other than clinical association is recorded or referred to in the bibliography.

There is also confusion on an important point. The report attributes dermatitis to the presence in the fur of incompletely oxidised products of para- or metaphenylendiamin. I showed, however, in the paper referred to above, that when either of these substances was treated with an oxidising agent, two products were formed, one soluble and irritating, and the other insoluble and harmless, the latter being "Bandrowsky's base." and that it was not possible to convert the former into the latter by further oxidation. All that is required is that the fur should be thoroughly washed with water. I am informed that in the case of the furs now on sale special care has been taken to eliminate this danger. It would be a pity, therefore, if as a consequence of the alarm that this report has caused in the minds of the laity, as evidenced by the comments in the daily press, those people who buy dyed rabbit fur should be unjustifiably deprived of a valuable source of warmth. In the Ministry's report only 1000 cases were recorded up to July, 1923, and as 14,000,000 dyed coney skins were consumed in this country in the making of fur garments during the period covered by the report, it follows that the risk is infinitesimal. In addition, a large number of fur garments were imported in a ready-made state. It is unfortunate that the report does not mention this.

Inasmuch as the family doctor is not infrequently consulted about the risk of disease from the wearing of fur, it is as well that these facts should be brought to the notice of the profession. Fur dermatitis is quite a definite disease with a specific cause, and it should not be assumed that other lesions, such as seborrhœa, occurring in the wearer of a fur garment are necessarily cases of fur dermatitis.

I am, Sir, yours faithfully,
A. KNYVETT GORDON, M.B., B.C., B.A. Camb.
Bedford-square, W.C., Oct. 13th, 1924.

THE TOXÆMIAS OF PREGNANCY.

To the Editor of THE LANCET.

SIR,—Will you permit us to reply, as briefly as possible, to the strictures passed by your reviewer (THE LANCET, Oct. 4th, p. 701) on our small volume dealing with the above subject? He appears to object strongly to the terms "pre-eclampsia" and "nephritic" toxæmia, and indeed to any attempt to differentiate the two conditions. To deal adequately with the subject some rudimentary knowledge of the American literature is unfortunately necessary, since most modern investigations of the toxæmias are the product of American clinics. With such knowledge, his assertion that we have done a disservice to medicine "by endeavouring to introduce a new title" for the group which we label "nephritic toxæmia" becomes preposterous. The term has been current in American text-books for many years. It is employed by such an acknowledged authority on Obstetrics as Whitridge Williams in his well-known text-book (1917, 1923), and among other writers on the subject by De Lee (1918) and Slemons (1918). We cannot, therefore, plead guilty to introducing this, to him, offensive term. For the use of the word "pre-eclampsia" we can again refer him to the same authorities and assure him that in America the term has attained a wide currency. We have taken special care to point out that the pre-eclamptic condition does not invariably terminate in eclamptic convulsions, though such care hardly seemed necessary in view of the generally accepted meaning of the term. The use of the term pre-eclampsia in America has led to neither of the mischievous, but diametrically opposite, results which he fears may follow its employment in this country. If he objects to any attempt to differentiate by modern methods the conditions which may produce albuminuria in pregnancy, we can only reply that after devoting some attention to the subject we have come to the conclusion that such differentiation serves a useful purpose both in treatment and prognosis. Our preface will show that we are fully prepared to revise our views, but such revision will be the result of fuller knowledge of the subject, rather than of unsupported assertions or the *obiter dicta* of "obstetricians of 20 years ago."

We will not trespass on your valuable space by any discussion of the question of pernicious vomiting. The matter is largely one of definition, and the definition of the disease which we have given was intended to rule out the so-called neurotic vomiting. In classifying raised blood pressure and urinary changes as symptoms we are in unrepentant, though possibly erroneous, agreement with the well-known text-book of the late Sir William Osler. A slight knowledge of the etymology of the term suffices, however, to show its wide applicability.

We are, Sir, yours faithfully,
O. L. V. DE WESSELOW.
J. M. WYATT.
Oct. 10th, 1924.

*** We welcome warmly any attempt to differentiate between eclampsia and nephritis; but we fear that by encouraging the use of vague titles the authors may perpetuate that lack of precision in diagnosis which at present leads to disaster in some cases and the unnecessary termination of pregnancy in others. Many practitioners have never realised that a group of cases of albuminuria in pregnancy are merely due to nephritis lit up afresh. The authors' investigations have done much to illuminate this fact; their chosen nomenclature threatens to obscure it.—ED. L.

Obituary.

GEORGE ENSIGN BUSHNELL, M.D. YALE,

COLONEL, MEDICAL CORPS, U.S. ARMY (RET.).

IN the passing of Colonel George Bushnell, the select band of workers which, following in the footsteps of Trudeau, has shed lustre upon American medical science by the study of tuberculosis loses one of its most distinguished members. Bushnell graduated at Yale in 1876 and took his M.D. at that University in 1880, entering the army in 1881. After a period of service in various frontier posts and some administrative work in the Surgeon-General's office at Washington during the Spanish-American War, his career was interrupted by an event which might well have restricted or prevented the development of his professional activities. He was stricken with pulmonary tuberculosis in 1900. But in the case of Bushnell this disability appears to have given just that direction and guidance which was destined to lead him on to further distinction and utility. In 1903 he assumed duty as Commanding Officer of the Army Sanatorium at Fort Bayard, and started that intensive study of tuberculosis which was to place him in the front rank of his profession. This appointment led to one of still greater importance, for in 1917 he was transferred, once more, to the Surgeon-General's office and placed in charge of the section of tuberculosis, a post which he held through the strenuous time of America's preparation for, entry into, and demobilisation after the European war. Colonel Bushnell's most important contribution to medical science is his work, "A Study in the Epidemiology of Tuberculosis, with special reference to Tuberculosis in the Tropics and of the Negro Race."[1] This book deserves to become one of the classics on epidemiology, since it brings the weight of its author's knowledge and experience to support a view of disease which, especially important in tuberculosis, has, at the same time, a wide bearing upon bacterial dissemination in general and the response of man and animals to the infective elements of their environment. Unlike most tuberculosis workers, Bushnell had had to do not merely with the disease as it is seen in civilised communities, but also in its manifestations in the virgin soil of American Indians and in the relatively non-resistant negroes of the Southern States. This opportunity was not lost upon him. To his prepared mind, the contrast between the clinical and epidemiological picture under these varying conditions carried its true lesson.

In the book above quoted Bushnell wrote: "We cannot comprehend how a general tuberculization 'influences the dissemination' and progress of tuberculous disease until we know how communities and individuals fare who have not had previous acquaintance with the tubercle bacillus." He recog- ised to the full the importance of previous contact vith, and infection by, the tubercle bacillus in raising he resistance against reinfection and in modifying he course of the disease when it becomes developed o the threshold of clinical manifestation. Physical igns, for him, assumed their proper character as henomena of resistance. "Râles," he says, "constiute the auscultatory evidence of inflammatory eaction to the poisons of the tubercle bacillus. . . . hey are the best evidence that the lesion is resisting ts foe." In his capacity as chief of the tuberculosis ection at Washington, Bushnell was able to focus is previous observations on tuberculosis so as to lluminate the problem of this disease as affecting an rmy in the field. A notable paper from his pen on he subject of Tuberculosis Epidemiology in the Vorld War appeared in the *Military Surgeon* of Tovember, 1922. Here he pointed out that, so far s concerns European or American troops, "the xperience of the best clinicians has led them to elieve that tuberculosis is not disseminated under the onditions of army life. . . . Those who will break own under the conditions of military service are, in ery large measure, those who bring their tuberulosis with them into the service."

---

[1] New York: William Wood and Company. 1920.

These brief quotations suffice to show that Bushnell as an original and independent thinker, and hat his studies on epidemiology had led him, ndependently, to the same conclusions as had een reached under similar conditions by several uropean workers such as Metchnikov, Calmette, nd Sanarelli.

Those who had the privilege of meeting Colonel ushnell when, though weary from a life of work and udy and feeble from a long struggle with disease, he ttended the International Conference on Tuberulosis in London in 1921, will recollect the quiet, elf-effacing courtesy of his manner, the sudden ash of interest as some point of epidemiological nportance emerged in the discussion, the keen, ighly-trained mind that was evident when he spoke pon the disease which had formed his life-study. is contributions to our knowledge of tuberculosis will ve.

IR CHARLES CAMERON, BART., M.D., M.CH., LL.D. DUB.

Sir Charles Cameron, formerly Member of Parliaent for Glasgow, who died on Oct. 2nd at the age 82, was the son of John Cameron, a newspaper roprietor of Glasgow and Dublin. Born in 1841, e was educated at Madras College, St. Andrews, d later entered Trinity College, Dublin, where he as senior moderator and gold medallist in 1862, d obtained the first place in the M.B. and M.Ch. aminations in the same year. After doing postaduate work in Paris, Berlin, and Vienna, he decided enter the ranks of journalism, and became in 1864 litor of the *North British Daily Mail*, a Glasgow riodical, of which his father was part proprietor. he following year he obtained the degrees of M.A. d M.D. Dub., and received the LL.D. in 1870. his capacity as editor he worked for ten years, and as an assiduous student of social reform. He soon on for himself a name in the political world in the est of Scotland as an advanced Liberal, and when stood for Parliament in 1874 he was returned at e head of the poll for the undivided constituency Glasgow, which then returned three Members. t the General Election of 1880 he was again returned, d after the city was divided into separate constiencies he was elected in 1885 for the College Division, hich he represented for ten years. He lost his at in 1895, but from 1897 to 1900, when he retired the General Election, he represented the Bridgeton ivision. His political activities included the placing no fewer than nine separate Acts of Parliament the Statute Book, among them the adoption the sixpenny telegram, the passing of the Inebriates cts, the Acts abolishing imprisonment for debt in Scotland, for conferring the municipal franchise on women in Scotland, and for various reforms in the Scottish licensing laws.

In 1893, the year in which he was created a baronet for his able Parliamentary work, he was appointed chairman of the departmental committee on the coastwise transit of cattle; in 1894 he was chairman of the departmental committee on habitual offenders in Scotland, and in 1895 served on the Royal Commission on the liquor licensing laws.

Sir Charles Cameron was the author of a number of pamphlets on medical, social, and political subjects, vaccination and the prevention of cholera being among them. In 1881 he was president of the Health Section of the Social Science Congress, and at the annual meeting of the British Medical Association at Belfast in 1884 presided over the Section of Public Health, taking for his presidential address the subject of the cholera microbe and how to meet it. This address evoked much interest, and was afterwards published in pamphlet form. A justice of the peace and a deputy lieutenant of the county and city of Glasgow, Sir Charles Cameron, when he retired from active Parliamentary work, was presented by his many friends and admirers with his portrait as a recognition of his high personal character and his services to the city of Glasgow. He married first, in 1869, Frances Caroline Macauley, who died in 1899, leaving one daughter; and secondly, in 1900, Blanche, daughter of Arthur Perman, of Stoke Newington, who survives him with one daughter and a son, born in 1903, who succeeds to the baronetcy.

EDGAR REID, M.R.C.S. ENG.

Dr. Edgar Reid, honorary gynæcologist to the Swansea Hospital, died at his residence in Swansea on Sept. 19th as a result of septic infection of the finger after performing an operation about ten days previously. He was 59 years of age and was born in Swansea. After qualifying at Guy's Hospital he returned to Swansea to join the late Dr. H. A. Latimer in general practice. When the latter retired Dr. Reid gave up general work and specialised in obstetrics and gynæcology and was in charge of that department at the Swansea Hospital. He was also a consultant of the Aberavon and Maesteg Hospitals. During the war he was on the staff of the 3rd Western Hospital at Cardiff. A colleague writes: "He was undoubtedly and deservedly the most popular member of the medical profession in West Wales. While at Guy's he was captain of the cricket team and also played football for the hospital. Later he played for Glamorgan county at cricket and for Swansea at football. As a bat and cover-point he has never been excelled in South Wales. The present generation will remember him best as a golfer, and on two occasions he was runner-up of the semi-final Welsh golf championship. He was the kindest of men and a loyal friend." Dr. Reid leaves a widow and a daughter. His only son was killed in action in France in 1917.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 4TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 52; scarlet fever, 2040; diphtheria, 1007; enteric fever, 137; pneumonia, 533; puerperal fever, 35; cerebro-spinal fever, 7; acute poliomyelitis, 32; acute polio-encephalitis, 3; encephalitis lethargica, 52; typhus fever, 1; continued fever, 3; dysentery, 3; ophthalmia neonatorum, 110. There were no cases of cholera or plague notified during the week. The case of typhus fever was notified (in error) from Bethnal Green (see p. 817).

Deaths.—In the aggregate of great towns, including London, there were 5 deaths from enteric fever, none from small-pox, 8 from scarlet fever, 30 from diphtheria, 12 from measles, 25 from influenza. In London itself the diphtheria deaths numbered 18, and the deaths from infantile diarrhœa 28.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Defeat of Government and Dissolution.

ON Wednesday, Oct. 8th, the Government were defeated by 364 votes to 198 on a Liberal amendment to a vote of censure moved by the Conservatives. The amendment called for the appointment of a Select Committee of the House of Commons to inquire into the withdrawal of the prosecution at the instance of Sir **PATRICK HASTINGS**, the Attorney-General, of Mr. J. R. **CAMPBELL**, the acting editor of the Communist newspaper the *Workers' Weekly*, for publishing an article inciting the troops to mutiny. After the announcement of the results of the division the Prime Minister moved the adjournment of the House of Commons till the following day. On Thursday, Oct. 9th, Mr. **RAMSAY MACDONALD** announced in the House of Commons that he had advised the King to dissolve Parliament, and that the General Election would be held on Oct. 29th. After the Lords had passed the Irish Boundary Commission Bill through its remaining stages, the Royal Assent was given to that measure and Parliament was prorogued by Royal Commission.

HOUSE OF COMMONS.

WEDNESDAY, OCT. 8TH.

Admiralty Medical Department.

Mr. **OTHO NICHOLSON** asked the Parliamentary Secretary to the Admiralty whether he was aware of the office conditions in the medical department, where one room used as a repository was badly ventilated, poorly lighted, dusty and dirty, and another room used for typing was unfit for human habitation, especially in winter months, and clerks were still working in draughty corridors; whether the department observed any quota of cubic space per person, and, if so, what it was; and whether he would investigate the grievances of the staff with a view to immediate action.—Mr. **AMMON** replied: If the Admiralty had been aware that the staff of the medical department had any complaint to make in regard to their present accommodation they would, of course, have inquired into it and have communicated with H.M. Office of Works on the subject, but in view of the hon. Member's question I will now refer the matter to my right hon. friend.

Exemption from Vaccination.

Mr. **ERNEST SIMON** asked the Minister of Health whether, in view of the strongly expressed opinion of the chief medical officer of the Ministry of Health that the public had taken dangerous advantage of the facilities for obtaining exemption from vaccination, he would reconsider the action taken by him on August 30th in rescinding the Vaccination Order of 1923 and thereby making exemption easier.—Mr. **WHEATLEY** replied: The answer is No, Sir.

Cobb Committee and Lunacy Regulations.

Mr. **ROBERT RICHARDSON** asked the Minister of Health how soon he proposed to carry into effect the recommendation of the Cobb Committee appointed by his department—viz., that Section 79 of the Lunacy Act be posted up in the waiting-rooms of public asylums so that friends as distinct from relatives of the patient might be made acquainted with the privilege, to which they were entitled by the Act, of making application to the visiting committee for the discharge of inmates, a privilege of which they had hitherto been kept in ignorance.—Mr. **WHEATLEY** replied: I would refer the hon. Member to the answer given to the hon. Member for Pontypool on March 12th, 1923, that in the opinion of the Board of Control there are serious objections to a general rule requiring that this section should be posted up in waiting-rooms. The revised rules of the Commissioners of the Board of Control, which are now awaiting statutory approval, provide that on the admission of every pauper lunatic to an institution for lunatics a notice shall be sent to all persons whose names appear as relatives or friends of the patient in the statement of particulars accompanying the reception order as to the times and conditions of visitation; and in such notice shall be embodied the substance of Section 79 of the Lunacy Act, 1890.

Compensation for Silicosis.

Lieut.-Commander **FLETCHER** asked the Home Secretary if a decision had yet been arrived at as to whether silicosis, or potter's asthma, should be scheduled under the Workmen's Compensation Act.—Mr. **HENDERSON** replied: The matter is one which would have to be dealt with by a scheme under the Workmen's Compensation (Silicosis) Acts, and I am advised that before a scheme under those Acts can be drawn up, a special inquiry involving the medical examination of a considerable number of workers in the industry must be undertaken. I am hoping to arrange for the commencement of this inquiry at an early date.

### *Maintenance of Pauper Lunatics.*

Lieut.-Commander **FLETCHER** asked the Minister of Health if he was aware that the existing grants to boards of guardians at 4*s.* per head for maintenance of pauper lunatics is totally inadequate; and if he proposed to introduce legislation to remedy this state of affairs.—Mr. **WHEATLEY**, replying, said: I cannot undertake to introduce legislation for the alteration of this grant at the present time.

THURSDAY, OCT. 9TH.

Progress of House Construction.

Captain **BOWYER** asked the Minister of Health how many houses up to date were approved; how many were under construction; and how many had been completed under the Housing Act, 1923.—Mr. **GREENWOOD** (Parliamentary Secretary to the Ministry of Health) replied: 161,441 houses have been authorised to date under the Housing, &c., Act, 1923. On Sept. 1st, the latest date for which information is available, 26,347 houses had been completed and a further 50,524 were in course of construction.

Pensioners' Allowances for Out-patient Treatment.

Mr. **TREVELYAN THOMSON** asked the Minister of Pensions whether he would revise the regulations which prevented an ex-Service man who was undergoing out-patient treatment from receiving any monetary allowance even when the disability for which he was being treated prevented him from following his normal occupation.—Mr. F. O. **ROBERTS** replied: I fear that I am not in a position to accept my hon. friend's suggestion. I may, however, state that at the present time there are on an average over 6000 men undergoing out-patient treatment who are in receipt of full allowances under Article 6 of the Royal Warrant.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At examinations recently held the following candidates were successful:—

DIPLOMA IN PUBLIC HEALTH.

Stuart F. Allison, Charles C. P. Anning (Trin.), Constance E. Appleton, William H. I. Bathurst, George R. H. Chell, *Robert P. Cormack, Isabelle A. Deans, Alice M. S. Dewar, Herbert S. Griffith, Thomas W. Hill, *Oswald R. Horwood (Corp. Chr.), Lionel J. Kahawita, Henry J. R. Kirkpatrick, *Frederick McKibbin, Guy Meadows, Margaret J. Rennet, Emily V. Saunders-Jacobs, John Scott, Ramtaran Sen, Robert S. Taylor (Down), Ann W. Turnbull, and John Wyllie.

* Distinguished in the application of Sanitary Science.

DIPLOMA IN HYGIENE.

*†Riad Hilmy Bestawros (non coll.), Ali Foad (non coll.), Mohamed Abdel-Hamid Gohar (non coll.), Azif Youssef Mankarius, (non coll.), *Abdel Shafi Mohammed (non coll.), ‡Mohammed Nazif (non coll.), Ismail Yousry (non coll.).

* Distinguished in the Principles of Hygiene.
† Distinguished in Bacteriology.
‡ Distinguished in the application of Sanitary Science.

UNIVERSITY OF LONDON.—The President of the Board of Education has instituted a Departmental Committee to deal with the final report of the Royal Commission on University Education in London dated March 27th, 1913, and, having regard to present circumstances and after consultation with the persons and bodies concerned, to indicate what are the principal changes now most needed in the existing constitution of the University of London and on what basis a Statutory Commission should be set up to frame new statutes for the University. The following were appointed as members of the committee by the President of the Board of Education: Lord Ernle (chairman), Sir Robert Blair, Dr. H. L. Eason, Mr. H. B. Lees-Smith, Sir Henry Miers, Prof. A. F. Pollard, Sir Amherst Selby-Bigge, Bart., Miss K. Wallas, and Mr. S. H. Wood (secretary). With reference to the appointment of this committee a communication dated Sept. 15th, 1924, was received by the Senate of the University of London from the President of the Board of Education, and on the afternoon of Oct. 9th an extraordinary meeting of the Senate was held, with Prof. E. A. Gardner in the chair, to consider the communication, when the following resolution was passed unanimously:—

> That the President of the Board of Education be respectfully reminded that the Senate was not consulted as to the reference to the Haldane Commission, nor represented upon it, nor gave evidence before it; and that, having regard to the successful progress of the University since the Report of that Commission the Senate is of opinion that such changes in the organisation of

ie University as are necessary may be more readily effected by nendments promoted by the University than by a statutory vision of the University as constituted by the Act of 1898; ut that the Senate will be prepared to furnish through its ficers and appropriate Committees any information desired by ie Departmental Committee and trusts that the various bodies id interests represented on the Senate will receive a full pportunity of putting individually or collectively before the epartmental Committee their views on the matters under nsideration.

Royal College of Surgeons of England.—A uarterly meeting of the Council was held on Oct. 9th with ir John Bland-Sutton, the President, in the chair. On ehalf of the committee on the annual report of the ouncil, a draft copy of the report to be presented to the ellows and Members at the annual meeting on Nov. 20th as submitted and the report was approved and adopted.— Ir. Anthony Richard Charles Higham, lately a student at psom College, was nominated the thirty-second Jenks cholar.—A Sir Gilbert Blane Medal was awarded to the llowing medical officer of the Royal Navy: Surg.- ieut.-Commander Harold Boultbee Padwick, D.S.O., B.A., romotion Examination, 1924.—The President reported iat the Bradshaw Lecture on Some Clinical Aspects of arcinoma of the Breast would be delivered by Mr. Raymond ohnson on Nov. 6th, at 5 P.M., and that the Thomas Vicary ecture on Sir Richard Owen as Conservator would be elivered by Sir Arthur Keith on Nov. 1[illegible]th, at 5 P.M.—The iploma of Member was conferred upon Violet Alice Quilley, oyal Free Hospital, who has complied with the necessary y-laws.

Lidbetter, at the rooms of the Royal Society, Burlington House, Piccadilly, on Wednesday, Oct. 22nd, at 5 P.M., Major Leonard Darwin in the chair. Members of the Eugenics Education Society and all interested in the above subject are invited to attend.

Hunterian Society.—The first dinner meeting of the society will be held at Simpson's Restaurant, 2 and 3, Bird-in-Hand Court, 77, Poultry, Cheapside, on Monday, Oct. 20th, at 7.30 P.M. After dinner, about 8.30 P.M., Mr. H. W. Carson will deliver the presidential address on the Watershed of Medical Practice. The price of the dinner is 3*s.* 6*d.* (excluding wines).

Epsom College Memorial Chapel.—In consequence of the recent builders' strike the consecration of the Memorial Chapel at Epsom College, Surrey, has been postponed from Nov. 1st, 1924, to Saturday, Feb. 21st, 1925, when the Bishop of Winchester will perform the ceremony. It is hoped that the chapel will be in full use by the middle of next month.

London School of Dermatology.—The Chesterfield lectures, constituting a systematic course in dermatology, will be given at 5 P.M. on Tuesdays and Thursdays from October to March at St. John's Hospital for Diseases of the Skin, Leicester-square, W.C. An examination will be held at the end of the course, and the Chesterfield medal will be awarded to the best candidate, provided the required standard is reached. The syllabus and further particulars may be obtained from the Dean of the school.

St. Andrews Institute for Clinical Research, Fife.—Winter Session.—Papers dealing with Renal Efficiency will be read and discussed on Tuesday afternoons at 4 P.M. as follows: Oct. 21st, Anatomy and Embryology of the Kidney, Prof. D. Waterston; Oct. 28th and Nov. 4th, Physiology of the Kidney, Prof. P. T. Herring. Notice of the subjects of subsequent discussions will be published later. All practitioners are cordially invited to these meetings.

Mr. Warren Low was the guest of the Surgical Instrument Manufacturers' Association at their annual dinner held at the Holborn Restaurant on Oct. 10th. In acknowledging the toast for the guests he complimented British manufacturers upon the high standard of excellence reached by them in the surgical instruments they produced. He considered that British manufacturers had not only kept abreast of the times, but had presented to the world types, characteristics, and qualities which defied imitation.

Messrs. Bale, Sons and Danielsson are publishing the third Research Study in Medical History of the Wellcome Historical Medical Museum, being the Iconography of Andreas Vesalius (André Vésale), Anatomist and Physician, 1514–1564, a work which was projected to celebrate in Brussels in 1914 the fourth centenary of Vesalius's birth. The author, Mr. M. H. Spielmann, F.S.A., F.R.S.L., has added a number of notes, critical and bibliographical, and forewords are contributed by Prof. Paul Heger, Sir Arthur Keith, Prof. Harvey Cushing, and Dr. Tricot-Royer. The study is illustrated by 100 reproductions from paintings, pictures, engravings, sculpture, and medals.

West Riding Association of the Graduates of the University of Edinburgh.—The annual dinner will be held at 7.15 P.M. on Wednesday, Nov. 12th, at the Midland Hotel, Bradford. It is to be preceded by the annual general meeting at 6.30 P.M. The guest of the evening will be Prof. George M. Robertson, professor of psychiatry at the University of Edinburgh.

Dangerous Drugs.—A draft of the new regulations amending the Raw Opium Regulations, 1921, and the Dangerous Drugs Regulations, 1921 and 1923, under the Dangerous Drugs Act, 1920, has just been issued by the Secretary of State of the Home Department. The effect of the new regulations is to prohibit the diversion of consignments of raw opium and dangerous drugs passing through ports in Great Britain to destinations different from those to which the consignments were licensed from the country of export; and to modify in the case of prescriptions issued on National Health Insurance forms the requirements to be observed before a prescription for dangerous drugs is dispensed. Draft copies of the new regulations can be obtained on application to the Under Secretary of State, Home Office, Whitehall, London, S.W. 1.

Fifth International Congress of the History of Medicine.—This congress will be held at Geneva on July 20th to 25th, 1925, under the patronage of the Medical Society of Geneva. The following are the office-bearers:—President of Honour: Sir D'Arcy Power, K.B.E. (London). Vice-Presidents of Honour: Drs. P. Capparoni (Rome), D. Giordano (Venice), E. B. Krumbhaar (Philadelphia), Laignel-Lavastine (Paris), J. G. de Lint (The Hague), A. Patey (Geneva), J. D. Rolleston (London), Charles Singer (London), Mr. C. J. S. Thompson (London), and Dr. Tricot-Royer (Antwerp). President: Dr. Charles Greene Cumston (Geneva). Vice-Presidents: Dr. Ernest Wickersheimer (Strasbourg) and Prof. Andrea Corsini (Florence). General Secretaries: Drs. A. de Peyer (Geneva) and Emile Thomas (Geneva). Treasurer: Dr. Edouard Schauenberg. Subscriptions for members will be 15 Swiss francs; for Associates, 10 Swiss francs, which should be sent to the treasurer at the office of the General Secretariate, 20, rue Général Dufour, Geneva. Members will be entitled to a copy of the proceedings of the congress when published. A preliminary programme of the proceedings will be issued about Dec. 1st, and can be had upon application to the General Secretariat. A cordial invitation is extended to members of the profession interested in the subject to become members and take part in the meeting of the congress.

Donations and Bequests.—By will the late Mr. James Parr, of Higher Openshaw, Manchester, left, subject to life interests, £6000 Manchester Corporation Stock and £2600 Manchester Royal Exchange Building Stock to St. Mary's Hospitals, the Manchester and Salford Lying-in Hospital, the Manchester Maternity Hospital, and the Manchester Southern Hospital; and £15,000 between St. Mary's Hospitals, the Manchester and Salford Lying-in Hospital, the Manchester Southern Hospital, and the Manchester Maternity Hospital; £6000 to St. Mary's Hospitals, the Manchester and Salford Lying-in Hospital, the Manchester Southern Hospital, and the Manchester Maternity Hospital; and £6000 to Ancoats Hospital and Dispensary. Part of the residue of the estate will also be divided between St. Mary's Hospitals, the Manchester and Salford Lying-in Hospital, the Manchester Maternity Hospital, Ancoats Hospital and Dispensary, the Society for the Prevention of Cruelty to Animals, Manchester Branch, and Henshaw's Blind Asylum.—The late Mr. James Fieldsend, of Sheffield, left, among other bequests, by will £200 each to the Sheffield Royal Hospital, the Sheffield Royal Infirmary, the Jessop Hospital for Women, the Edgar Allen Institute, the Sheffield Children's Hospital, the Blind Institution, West-street, the Deaf and Dumb Institution, Charles-street, the Sheffield Branch of the Y.M.C.A., and the Queen Victoria Nursing Association, Sheffield. Subject to bequests totalling some £1200, and to certain life interests, he left the residue of his property equally between the Sheffield Royal Hospital, the Sheffield Royal Infirmary, the Jessop Hospital for Women, the Blind Institution, West-street, the Boys' Charity School, Sheffield, and the Girls' Charity School, Sheffield.—By the will of the late Dame Ada Elizabeth Jackson, of Ennismore-gardens, Westminster, S.W., the testatrix left £5000 to Cardiff Royal Infirmary in memory of her late husband, Charles James Jackson, with the request that a children's ward or wards shall be known as the "Sir Charles and Lady Jackson" Ward or Wards.—Miss Louisa Anne Townsend, of Alveston, Warwickshire, left £200 to the Stratford-upon-Avon Hospital, the Stratford-upon-Avon Nursing Home, and the Industrial Home, Stratford-upon-Avon.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Oct 21st.

GENERAL MEETING OF FELLOWS: at 5 P.M.
Ballot for Election to the Fellowship.

PATHOLOGY: at 8.30 P.M.
Presidential Address by Dr. J. A. Murray.

Wednesday, Oct. 22nd.

COMPARATIVE MEDICINE: at 5 P.M.
Presidential Address:
Mr. Frederick T. G. Hobday: The Section of Comparative Medicine.

Thursday, Oct. 23rd.

EPIDEMIOLOGY AND STATE MEDICINE: at 5.30 P.M.
Presidential Address:
Dr. John C. McVail: Progress in Preventive Medicine.

Friday, Oct. 24th.

STUDY OF DISEASE IN CHILDREN: at 5 P.M.
(Cases at 4.30 P.M.)
Cases:
Dr. Bernard Myers: Case demonstrating the Use of Pituitary Whole Gland in Chronic Constipation.
Mr. Denis Browne and Mr. Twistington Higgins: Congenital Hypertrophy of both Lower Limbs.
Dr. F. J. Poynton: Cases of Cœliac Disease with Glycosuria.
Other cases will be shown.
Communication:
Dr. B. E. Schlesinger: The Subsequent History of a Series of Cases Operated on for Pyloric Stenosis.

THE MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.
Tuesday, Oct. 21st.—8.30 P.M., Prof. Harvey Littlejohn:
(1) Judicial Hanging: A Humane Method of Execution.
(2) What is the Fatal Dose of Strychnine? Followed by a discussion.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, W.
Thursday, Oct. 23rd.—8.15 P.M., Sir Malcolm Watson: Observations on Malaria Control with special reference to the Assam Tea Gardens, illustrated by lantern slides. This will be preceded by a demonstration on Some Malaria-carrying Mosquitoes and their Larvæ.

THE TUBERCULOSIS SOCIETY, at the House of the Society of Medical Officers of Health, 1, Upper Montague-street, Russell-square, W.C.
Friday, Oct. 17th.—8 P.M., Dr. O'Donovan: Cutaneous Tuberculosis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
Monday, Oct. 20th to Sat. Oct. 25th.—Royal Society of Medicine. Lecture arranged by the Fellowship of Medicine and open to members of the profession. Mon., 5.30 P.M., Sir StClair Thomson: Cancer of the Larynx.—Bethlem Royal Hospital, St. George's Fields, S.E. Tues., 11 A.M., Dr. Thomas Beaton: The Psychoses. Sat., 11 A.M., Dr. Porter Phillips: The Medico-legal Aspect of Insanity.—Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C. Special Intensive Course.—London School of Hygiene and Tropical Medicine, Endsleigh-gardens. Tuesday and Thursday, 2 P.M., Clinical Demonstration by Dr. G. C. Low and Dr. Manson-Bahr.—Royal Free Hospital, Gray's Inn-road, W.C. Wed., 5.15 P.M., Dr. Heald: Lecture-Demonstration, The Medicinal Uses of Ultra-Violet Light.—St. Peter's Hospital, Henrietta-street, W.C. Clinical work and Lectures daily.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
Friday, Oct. 24th.—5 P.M., Prof. Arthur Keith: Museum Demonstration: Specimens illustrating the Common Kinds of Congenital Malformation.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
Tuesday, Oct. 21st.—4.30 P.M., Colonel L. W. Harrison: Cinematograph Demonstration, The Diagnosis and Treatment of Gonorrhœa in the Male.
Friday.—4.30 P.M., Dr. F. L. Provis: The Diagnosis and Treatment of Syphilis.
Daily: Medical and Surgical Clinics and Clinics in the various Special Departments, Surgical Operations, &c.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.
Tuesday, Oct. 21st.—5 P.M., Dr. A. W. Barber: Bacteriology and Mycology.
Thursday.—5 P.M., Dr. H. G. Adamson: General Ætiology.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, Oct. 20th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Bishop Harman: Eye Dept.

TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—11 A.M., Dr. Davies: Gynæcological Demonstration. 12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Dr. Pernet: Skin Dept.

THURSDAY.—11 A.M., Dr. Simpson: Gynæcological Wards. 12 noon, Dr. Scott Pinchin: Heart Diseases. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

FRIDAY.—12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Throat, Nose, and Ear Operations.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)

MONDAY, Oct. 20th.—(At the Shaw-street Hospital.) Dr. Gemmell: Gynæcological Diagnosis.

TUESDAY.—(At the Maternity Hospital). Dr. Willett: Antenatal Management.

WEDNESDAY.—(At the St. Paul's Hospital.) Dr. T. Stevenson: Eye Cases.

THURSDAY.—(At the St. George's Hospital.) Dr. F. Barendt: Skin Cases.

FRIDAY.—(At the Eye and Ear Infirmary.) Mr. H. E. Jones: Differential Diagnosis of Common Non-Inflammatory Eye Conditions.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

TUESDAY, Oct. 21st.—4.15 P.M., Mr. E. D. Telford: Diverticulitis.

FRIDAY.—4.15 P.M., Prof. R. B. Wild: The Treatment of Pain.

ROYAL INSTITUTE OF PUBLIC HEALTH, Russell-square, W.C.

(Course of Lectures on the Health of the Commonwealth.)

Burnley, Victoria Hospital.—H.S. £200.

ancer Hospital, Fulham-road, S.W.—Anæsthetist. Also H.S. at rate of £100.

entral London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. Asst. Anæsth.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. for six months. £62 10*s.*

Countess of Dufferin's Fund, Women's Medical Service for India.—Two Med. Women. Rs. 550.

Dumfries, Crichton Royal Mental Hospital.—Clin. Pathologist. £400.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Morning and Afternoon Cas. O.'s at rate £120. H.P. at rate £125. Also Res. M.O. £200.

Gesto Hospital, Edinbane, Skye.—Res. M.O. £300.

Gravesend Hospital, Kent.—Jun. H.S. £150.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Med. Reg. £100.

Hull, City and County of Kingston-upon-Hull.—M.O.H. £1400.

Leeds General Infirmary, Venereal Dis. Dept.—Two Asst. M.O.'s. £500 and £250 respectively.

Liverpool, West Derby Union.—Res. Asst. M.O. £200.

Manchester Homœopathic Institution, Gorton, near Manchester.—Res. M.O. £100.

Manchester Royal Infirmary.—H.S. for Aural, Gyn., and Ophth. Depts., at rate of £50.

Manor House Hospital, Golders Green, N.W.—Sen. H.S. £200.

Metropolitan Hospital, Kingsland-road, E.—Sen. H.P. and H.S. Jun. H.P. and H.S., two Cas. O.'s for six months. Each £50. Also Asst. P.

Monmouthshire County Council.—Two Asst. M.O.'s. £500.

Oswestry, Shropshire Orthopædic Hospital.—Two H.S.'s. Each £250.

Poplar Hospital for Accidents, East India Dock-road, E.—Sen. Res. O. £200.

Royal Chest Hospital, City-road, E.C.—P.

Royal Eye Hospital, St. George's Circus, S.E.—Hon. Asst. S.

Royal National Orthopædic Hospital, 234, Gt. Portland-street.—Two Hon. Asst. Surgeons.

Royal Naval Medical Service.—Surg. Lieuts. 25*s.* per day.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Hon. S. and Hon. Gynæcologist for Out-patients.

St. Mary's Hospital, W.—Director of the Dept. of General and Special Pathology, &c. £800.

St. Thomas's Hospital.—Pathologist. £500.

Stoke-on-Trent, North Staffordshire Infirmary.—Jun. H.P. £125.

Swansea General and Eye Hospital.—H.P. £175.

Wednesbury, Borough of.—M.O.H., &c. £800.

West Ham County Borough, Dagenham Sanatorium.—Asst. Res. M.O. £350.

West London Hospital, Hammersmith-road, W.—Surg. for Dis. of Women. Dermatologist. Also Hon. Medical Radiologist.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment at Caterham, Surrey.

Births, Marriages, and Deaths.

BIRTHS.

BRIMBLECOMBE.—On Oct. 9th, at Pranketts, Stoke-under-Ham, Somerset, the wife of S. L. Brimblecombe, M.R.C.S., L.R.C.P., of a daughter.

BUNTING.—On Oct. 4th, at "Warders," Tonbridge, the wife of Dr. G. L. Bunting, of a daughter.

ELLIOTT.—On Oct. 5th, at Mount Ephraim-road, Tunbridge Wells, the wife of Dr. Christopher Elliott, of a son.

HAYCRAFT.—On Oct. 14th, at 31, Cathedral-road, Cardiff, the wife of John Berry Haycraft, M.C., F.R.C.S., of a daughter.

MINNITT.—On Oct. 12th, at Kremlin-drive, Stoneycroft, Liverpool, the wife of Robert James Minnitt, M.B., Ch.B., of a daughter.

MARRIAGES.

JONES—VANE TURNER.—On Oct. 8th, at St. Peter's, Eaton-square, London, George Horatio Jones, M.R.C.S., to Muriel, only daughter of Mr. and Mrs. Vane Turner, formerly of Ealing.

DEATHS.

GIBSON.—On Oct. 12th, at King's College Hospital, James Albert Gibson, M.D., D.P.H., M.B.E., of Carisbrooke, Isle of Wight, aged 59.

LOCKYER.—On Oct. 9th, at 117A, Harley-street, Minnie Marie, the beloved wife of Cuthbert Lockyer, M.D.

LYLE.—On Oct. 9th, at Castellain-road, W., Thomas Lyle, M.D., late Medical Superintendent, Wonford House, Exeter, aged 85 years.

MORGAN.—On Oct. 11th, at Connaught-square, John Hammond Morgan, C.V.O., M.A., F.R.C.S., aged 77 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE LANCET: SUBSCRIPTION RATES.

INLAND	One Year	£2	2	0
	Six Months	1	1	0
	Three Months	0	10	6
ABROAD	One Year	2	10	0
	Six Months	1	5	0

Subscriptions not paid in advance are charged out at the published price of 1s. per copy, plus postage. Cheques and P.O.'s (crossed "Westminster Bank, Ltd., Covent Garden Branch") should be made payable to THE MANAGER, THE LANCET Offices, 423, Strand, London, W.C. 2.

Notes, Comments, and Abstracts.

CURRENT VIEWS ON INDIVIDUAL DIFFERENCES OF ABILITY.

Professor Spearman's Lecture.

The lecture on this subject, delivered by Prof. C. E. Spearman, Ph.D., F.R.S., at University College on Oct. 8th, constituted the first of a course of psychology open to the public. The problem, Prof. Spearman said, was one on which his department had been engaged for many years, during which time a number of points had been established, and these could now be collected to form a more or less complete whole. There were at the present time two doctrines on individual differences of ability: one known as the doctrine of intelligence, the other as the doctrine of faculties.

The Doctrine of Intelligence.

The first was the dominant one. Everyone referred to other people as more or less intelligent; there was a readiness to stigmatise some as bright and intelligent, others as stupid and dull. "Intelligence" was first used in the biological discussions on intelligence as contrasted with instinct. There was a tendency to regard the lower animals as possessing instinct, intelligence being reserved for man. A very important development was that which subjected intelligence to tests, especially in the work of Binet and Simon, and its application in the United States, where some two million men in the army in that country were tested from this mental standpoint. In the laboratory controlled by the lecturer, 30,000 clerks for the Civil Service had been tested.

But the views of Binet experienced a set-back at the hands of the biologists, largely owing to the difficulty of deciding precisely what was meant by intelligence and what was meant by instinct. Nor were authorities agreed as to tests, one writer declaring that a tester could not confront a person with school, the many situations in which he found himself in home, workshop, farm, and politics, calling for the exercise of the capacities which, in a summary way, were known as intelligence. A well-known German authority wrote that the problem of intelligence remained a problem still. Prof. Spearman's chief criticism of this concept of intelligence was that it was grossly equivocal. Did it include memory? Many said it did not, yet memory was included in the tests. And did it include sensory perception? Binet said it did not. Was imagination a part of it? Some denied it. Was language a part of intelligence? Some authorities regarded it as the essence of intelligence, and some considered attention as the very core of it. A similar importance was assigned to movement. A further criticism of the intelligence concept was that it was not an ultimate analysis. If a scientific treatment was aimed at, it was essential to proceed to ultimates, and not to be content with conglomerates.

Another important matter was the possibility of measuring intelligence. Of 14 authorities who met and advanced their definitions, not one used his definition in framing his tests. Some writers took up a passive attitude, being satisfied to remark that it was works which were tested, and this was all that was required. A more scientific aim was to make clear what was meant by "intelligence." One definition was "The power of adapting oneself to new situations"; but what was meant here by "adapting"? Biologically, it meant anything to preserve life; it certainly included a number of different processes. His own view was that there were certain ultimate operations, and one was the finding of relations, another was the finding of correlatives. But could these powers be measured? That was not easy. On the whole, he considered that this doctrine of intelligence was at present in a far from satisfactory state.

The Doctrine of Faculties.

The other great view on the subject was that known as the doctrine of faculties, and this also had many advocates, chiefly in Germany. That country possesses an institution at which every prospective employee on German railways undergoes psycho-testing over a period of two days, the tests covering nine faculties: power of combination, fixation of place-names and numbers, concentration, observation and carefulness, reckoning, doing many things at a time, speed in work, dexterity, speed in grasping facts. Dealing with the history of this doctrine, the lecturer said it dated back at least to Plato, for at that period it was known that the sense often led the observer astray. The ancients considered that the human being had two faculties—namely, sense and intellect. To this the faculty of memory was added, and, later still, the faculty of imagination or invention. The further one known as attention was recognised in the seventh century, and subsequently language and movement. It was easy to see, therefore, why "intelligence" was such an obscure and equivocal word. The speaker had analysed the works of 33 authors on this point; 15 of them advocated the faculty of perception, 16 that of intellect, 9 that of memory, 11 that of imagination, 10 that of attention, 6 that of movement, 3 of language, while 16 advocated fancy faculties, such as the picking out of the essential parts of a story.

A good deal of criticism had been levelled at this faculties conception, and the weighty objection urged by a German authority was, that imagination was spoken of as if it were one faculty, whereas it was well known that one person would be found to have imagination for one thing, and another person for another. The same was true of memory. This became very important from the point of view of formal training. Advocates of the teaching of mathematics claimed that the mental discipline implied was a great aid to all studies requiring concentration and reasoning; but it was found that the latter might not be as effectively employed in other studies as in mathematics, and the result of measurement of the capacity for one was not necessarily an index of capacity for another. The failure to recognise this was a weakness in the German testing system as applied to railway work.

It was important to realise that classification did not involve correlation. There were three chief causes of error here. We were misled by names; because things bore the same name, the tendency was to regard them as the same. Secondly, there was the fallacy which an ancient sophist illustrated by the contention that one ate raw meat because the meat bought yesterday was raw, and that was the meat one ate, therefore one ate raw meat. The third fallacy was to regard the act of perceiving as dissociated from the object perceived; the whole—the perception and the things perceived—must be considered together.

Summing up, Prof. Spearman said it seemed that the wisest course was to teach a person what one wanted him to be able to do efficiently, and that constituted an objection to formal training. The latter largely left matters to chance, it taught general subjects in the hope that it would enable the person taught to carry through to his special needs. Hence he thought that the people who objected to formal training were in the right; it seemed to be better to go direct to the special requirement and teach that.

"LISTON PALINGS."

Under this heading Dr. Herbert A. Smith has written to tell us of a bungalow situated somewhere on the south coast, bearing the name "Armistice," and fenced with long Liston splints with the oval foramina and notched edges uppermost. The builder is thought to be an ex-R.A.M.C. ambulance orderly.

PAINFUL CRAMPS.

To the Editor of The Lancet.

Sir,—Can any of your readers suggest a remedy for painful muscular cramps? A relative of mine who is crippled with rheumatoid arthritis is kept awake for hours every night by this distressing symptom, and there seems to be nothing that prevents its onset.

I am, Sir, yours faithfully,
E. W. Dewey.
Portsmouth, Oct. 7th, 1924.

TREATMENT OF MUCOUS COLITIS.

To the Editor of The Lancet.

Sir,—Can any of your readers tell me anything new in the treatment of mucous colitis, a complaint which is dismissed with very few words in systematic works on the practice of medicine, but which causes persons suffering from it a fair amount of pain and malaise, besides undermining the general health? The patient I have especially in my mind is a young man of healthy parentage who for some months has had mucus, casts, and occasionally a little blood passing per rectum. The sigmoidoscope and the X ray after a bismuth meal show nothing abnormal. There is sometimes a little distension and slight tenderness of the abdomen. He is keeping at work, but lacks some of his usual strength and energy physically and mentally. This is a complete contrast to his state a year ago.

I am, Sir, yours faithfully,
M. C.
Oct. 8th, 1924.

Dr. H. H. Taylor, of Hove, was on Oct. 9th elected by his colleagues on the town council to the aldermanic bench. He was first elected a member of the council in 1901. In January this year Dr. Taylor was placed on the Commission of the Peace for the borough.

THE

Harveian Oration

ON THE

DEBT OF SCIENCE TO MEDICINE.

Delivered before the Royal College of Physicians of London on St. Luke's Day, Oct. 18th,

BY ARCHIBALD E. GARROD, K.C.M.G., D.M., LL.D., F.R.C.P., F.R.S.,

REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF OXFORD; CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

MR. PRESIDENT AND FELLOWS OF THE COLLEGE,—More than two centuries and a half have passed since he most illustrious of our Fellows founded the Festival which we celebrate to-day, and directed hat an oration should be delivered by one of our number. Upon the long list of Harveian Orators are many names familiar wherever medicine is tudied, and amongst them those of my six most recent predecessors in my chair. I esteem it a great honour that you, Sir, should have thought me worthy to stand here to-day, and to deliver Harvey's message.

It will be my endeavour to follow the injunctions which he laid down; to commemorate the great men of the past, benefactors not only to this College but to the human race; to exhort our brethren to work together in peace and amity, and to urge them to pursue the study of our science, by methods of which he himself made such good use.

Ever since this College was founded its Fellows and Members have, generation by generation, brought heir several stones to the building of the house of medicine. Upon its Roll are names of "men in their generation famous, and in ours never to be forgotten," men of genius whose fame as discoverers and as pioneers, in medicine and in other branches of natural science, is world-wide and will never die; and of some highly distinguished in other walks of ife, great scholars, such as Linacre and Caius, poets and philosophers. Upon it, too, are names of generous benefactors to scientific education, such as John Radcliffe and Matthew Lee, and of commanding personalities, patrons of science, art or letters, such as Richard Mead, the Mecænas of his day.

But these great ones form only a small minority, and most of those upon our lists were men of lesser tature; but as teachers who handed down to heir pupils the treasures of their observation and experience, busy practitioners, keen observers, or men of varied culture few of them can have failed o add something to the sum of human knowledge. Yet many of their names recall no memory, or have attained to that most arid form of immortality, to serve as labels for malady or symptom. But, collectively, the work which they did counts for much, and those of us who are conscious that we shall eave no "footprints on the sands of time" may take courage from the thought that we too are helping to do the spade-work for some future Harvey.

On this occasion it is only fitting that special mention should be made of one born just three hundred years ago, and who, although, owing to a technical obstacle now long obsolete, he was not a Fellow of his College, held its licence; and we may associate n our celebration the names of William Harvey, he physician to King Charles and the immortal ounder of modern physiology, and Thomas Sydenham, he soldier of the Parliament, who did for clinical medicine what Harvey did for physiology, and brought it back from the realm of fancy to the bedside study of signs and symptoms. These two men, Harvey and Sydenham, each pre-eminent in his own line, were wholly unlike in their outlook, and although contemporaries are not known ever to have met.

Sydenham, at the mention of whose name the illustrious Boerhaave used to raise his hat, has been called the English Hippocrates, and by this College, on his monument, "medicus in omne ævum nobilis." Certainly no man ever had, in greater degree, the gift of conveying, in a few sentences, a vivid picture of a morbid state, and even though we may rejoice that those dear to us are no longer treated in accord with his prescription, we realise that he opened a new era of therapeutics. To him must be assigned a high place among our benefactors.

The history of medicine traces back to the birth of our race, and even beyond, for we know that the lower animals have therapeutic instincts. From the outset treatment has been shaped by prevalent notions of the nature of disease, and maladies provoked by the enmity of a primitive deity, or by the malicious magic of a fellow creature, are only likely to be cured by magical methods. In Osler's words: "To a very definite but entirely erroneous pathology, was added a treatment rational in every respect, had the pathology been correct." The primitive medicine and the art of the medicine-man survive, to this day among the savage races of the earth, and he would be a bold man who should deny their survival amongst those races which regard themselves as the highest products of civilisation. Are any of us wholly free from such ideas?

For ages medicine has striven to shake off her bonds, and to attain to the status of a science. The first act of the drama was staged in ancient Greece. We know well that the true spirit of inquiry, the desire for knowledge for its own sake, was innate in that wonderful race, of which the intellectual life centred around the city in which the people "spent their time in nothing else, but either to tell or to hear some new thing." The legacy of Greece embodies not only the Parthenon and the Erechtheum, the sculptures of Pheidias and Praxiteles, the plays of Æschylus and Euripides, the thoughts of Socrates and the works of Plato. Greece gave us also Aristotle and Hippocrates. Only the true spirit of science could have prompted the minute and accurate research into the structure and functions of living things which are embodied in the writings of Aristotle, or the pictures of disease and its symptoms to be found in the clinical records of Hippocrates. Do we not still speak of the "facies Hippocratica" and of Hippocratic succussion?

We cannot doubt that there were forerunners of Aristotle, nor that much of the knowledge embodied in his books had been collected by lesser men. Nor can we doubt that there were scientific physicians before Hippocrates, men of the schools of Cnidus and Cos, some of whose writings are included in the Hippocratic corpus. Indeed, Aristotle, whose lifetime overlapped that of Hippocrates, bears witness to this, when he speaks of physicians as men who usually base their medical theories upon principles derived from physics. We must rather suppose that, like other men of genius, Hippocrates illuminated and crystallised the floating knowledge in the atmosphere of the Asklepieion. But Hippocrates was something more than a man of science, for when we read what he has written we realise that the most cherished traditions of our profession, the rules of its conduct, were inherent in the Father of medicine, the author of the Hippocratic oath.

When, at a later period, the centre of Greek medicine shifted to Alexandria, Erasistratus and Herophilus had opportunities for the practical study of human anatomy such as none had before them; and in the second century of our era, the Greek tradition culminated in the life and writings of Claudius Galen, a great physician, a true enquirer of nature, author of many treatises, imbued with the spirit of Hippocrates, but not so great as he. It was the strange fate of this man to be set up as an oracle, to be regarded for more than a thousand years as infallible and his statements as admitting of no appeal. Then after Galen the curtain falls, to be rung up again only in the sixteenth century of our era.

During that long inter-act the races which had overthrown and over-run the empire of Rome were being educated *de novo*, to appreciate the culture which they had destroyed. Meanwhile, the keeping of the works of the ancient physicians passed to the Arab races, and for centuries were only known in Syriac or Arabic translations, or in retranslations from those tongues into Latin. Then in the end science stirred in her sleep in the thirteenth, and finally reawakened in the sixteenth century. There was indeed much leeway to be made up. Even as late as in the year 1559 Dr. John Geynes was cited before this College because he impugned the infallibility of Galen and was obliged to sign a solemn recantation of his error:—"Ego Johannes Geynes fateor Galenum, in iis quæ proposui contra eum, non errasse." Surely, in the Elysian fields, the shade of Galen chuckled!

Great as were the achievements of the fathers of medicine, they began to construct their edifice with the attics. Their anatomy was almost wholly that of the lower animals, and the physiology of Galen seems to us grotesque. The sciences upon which anatomy and physiology rest were hardly yet born. If medicine were to be established upon a scientific basis the structure needed to be firm from the ground upwards, and from the sixteenth century onwards, the foundation sciences, and those which form the lower stories, have been cultivated and advanced, largely by medical men who saw them to be essential to the progress of their own science and art.

So medicine, oldest of applied sciences, older indeed than the sciences applied, has through the ages furthered the growth of natural knowledge. How profound her influence has been, and how it has been exerted, it is my present aim to show.

Research and education are closely linked, but whereas from their earliest days there have existed, in the universities of Europe, the three professional faculties of Divinity, Law, and Medicine, that of Natural Science is of quite recent development. For the student with a scientific bent two paths were open; he might either attach himself to the Faculty of Medicine, or might approach his chosen studies by way of mathematics.

Even down to the seventeenth century, or later, the university course in medicine was almost wholly theoretical. The Professor expounded to his pupils the writings of Hippocrates and Galen, together with those of some of the great Arabians, such as Avicenna and Rhazes. Such were the duties assigned by Linacre to his lecturers at Oxford and Cambridge, and those of the Regius Professors at those ancient seats of learning. Thomas Molyneux (1661–1733) a young graduate of Dublin, where he was afterwards Professor of Medicine, visited Oxford in 1683, and heard the Regius Professor, Dr. Luff, "read on the first aphorism of Hippocrates in the Physic School; where giving an account of the shortness of man's life since, and the length of it before the flood, he made up of Mr. Burnett's fancy, not at all altered but in the word." No wonder that Molyneux was not diverted from his purpose to continue his studies at Leyden, where clinical medicine was being taught in a university clinic. Elsewhere clinical knowledge was acquired by attendance upon the practice of a physician or surgeon, a system of apprenticeship which has this to its credit that out of it has grown the English system of bedside instruction to small groups of students. The first attempt to start clinical teaching within the university was made in Padua in the late sixteenth century, but the first organised clinic was that in Leyden, started in about the year 1630.

The study of science for its own sake, apart from any professional applications, began again in the sixteenth century, and was active in the century which followed. In this country Oxford took a large part in the renascence of pure science. There Robert Boyle, the "father of chemistry," set up his private laboratory in 1654; and around John Wilkins, Warden of Wadham, the college of Mayow and Sydenham, and one to which science and medicine owe much, there gathered a group of men eager for the advancement of natural knowledge, who, with the members of the "Invisible College" in London, formed the nucleus of the future Royal Society. In the same century chairs of astronomy, natural philosophy, anatomy and botany were founded in Oxford, and the Botanic Garden was established. In 1657, Thomas Millington (1628–1704) a President of this College, was made Sedleian Professor of Natural Philosophy, and the first Savilian Professor of Geometry and Astronomy, John Bainbridge (1582–1643) was also one of our Fellows.

How large a part members of our profession played in this reawakening of science is shown by the large proportion of medical men among the original Fellows of the Royal Society. Of the total of 115, which included Peers, Clerics and distinguished people such as John Evelyn and Samuel Pepys, only a small proportion were men of science in any strict sense, and of these no less than 25 were Doctors of Medicine, whilst 21 were Fellows of this College.

In the reawakening of medical science Italy took the lead, and especially in the study of anatomy. Of her universities, Padua, under the enlightened rule of the Venetian Republic, became the chief centre of medical teaching in Europe, and thither repaired the pick of our English students to profit by teaching such as they could not obtain at home. Later, when the star of Padua paled for a time, Leyden took its place as the cynosure of students of medicine.

Of the professions open to him in former centuries that of medicine would obviously make most appeal to the youth of scientific bent, and as L. C. Miall puts it in his book on "The Early Naturalists":—

> "The medical school furnished the only regular training for the naturalist, whilst he found in the medical profession the likeliest means of earning his bread."

In his Rectorial Address to the University of Aberdeen, delivered in 1874, Huxley brought out the same point, with even wider application, when he said:—

> "Within my recollection, the only way in which a student could obtain anything like a training in physical science was by attending the lectures of professors of physical and natural science attached to the medical schools."

Still more striking is the following passage from the same address:—

> "In the days when all the innumerable applications of physical science to practical purposes were non-existent even in dreams; days which men living have heard their fathers speak of, what little physical science could be seen to bear directly upon human life lay within the province of medicine. Medicine was the foster-mother of chemistry, because it had to do with the preparation of drugs and the detection of poisons; of botany because it enabled the physician to recognise medicinal herbs; of comparative anatomy and physiology, because the man who studied human anatomy and physiology for purely practical purposes was led to extend his studies to the rest of the animal world."

Now that the practical applications of science are so far greater even than when these words were spoken, and a course of scientific training is necessary or desirable as a preparation for so many walks of life, there have sprung up schools of physical science of which the Royal School of Mines and the College of Chemistry, now fused into the Imperial College of Science, were the earliest to be established in this country. Our universities also teach science in all its branches, and grant degrees therein. In a word, science has been weaned from its foster-mother.

Seeing, then, that in the past medicine has supplied opportunities of education for students of natural philosophy and natural history, and has, at the same time, supplied a stimulus to their researches, it need cause no surprise that our profession can claim, amongst its most honoured members, not a few whose work has inaugurated new epochs in widely diverse branches of natural knowledge.

At first sight it would appear that astronomy, to which the natural approach is through mathematics, is as remote from medicine as any science can be; but there was a time when the pseudo-science of astrology supplied a close tie between the study of the stars and that of disease. The mediæval physician was profoundly influenced by the horoscope of his patient, and studied the motions and conjunctions of the planets to obtain such help in diagnosis and prognosis, as is afforded nowadays by the blood-count or electro-cardiogram. He was expected to have some knowledge of astrology, and even in the sixteenth century there were amongst our Fellows such men as Thomas Twyne (1543–1613), who gained more fame as an astrologer than as a physician, and some note as a poet. True medical astronomers, on the other hand, have been few in number, but Nicolas Copernicus (1473–1543), who revolutionised man's ideas of the universe, was a physician, and amongst lesser ights, mention may be made of our Fellow John Bainbridge.

Another science which has little contact with medicine is geology, save in so far as the nature of soils has bearings upon public health; but medical men have played very important parts in its advancement. Thus, Nicholas Steensen, commonly called Steno (1638–1686), who discovered the parotid duct which bears his name, may be described as one of he founders of geology and mineralogy. Most of his active life was spent in Florence, where he held he post of physician to two successive Grand Dukes. Of him von Zittel wrote, in his History of Geology, hat he was the first who sought to solve geological problems by inductive reasoning. He threw much ight upon the formation and structure of crystals, and as Leonardo da Vinci had done a century and a half earlier, he maintained that fossils are the actual emains of animals and plants of former epochs. He nded his life as a Catholic bishop, and his ascetic habits undermined his health. This brilliant Dane is ntitled to rank among the great ones of science, as anatomist, geologist, mineralogist, and physician, but his researches, so far in advance of his time, nly received their due recognition after much f his work had been done over again by later nvestigators.

John Woodward (1665–1728), Professor of Medicine t Gresham College, and Fellow of this College, also olds a distinguished place in the annals of geology. By his observations he acquired a most extensive nowledge of the structure of the earth's crust, and ad learnt much as to the superposition of the various trata, but he propounded a fantastic hypothesis that he whole globe had been taken to pieces at Noah's ood, and that from the resulting "promiscuous mass" the various strata had been deposited in uick succession. He bequeathed his collections to he University of Cambridge, where they form the ucleus of the museum which bears his name. Woodard was less eminent as a physician than as a eologist, and was evidently a quarrelsome fellow, or he forfeited his fellowship of the Royal Society ecause he insulted Sir Hans Sloane, to whom he efused to apologise; and a quarrel with Mead, over the treatment of small-pox, led to a passage of rms, in which the sword of Mead but the tongue f Woodward gained the mastery. "Take your life," aid Mead; "anything but your physic," was the eply. The celebrated James Hutton (1726–1797), so, who propounded the rival, and sounder theory hat the moulding of the crust of the earth has een effected gradually, by processes such as re now at work, was a Doctor of Medicine of eyden, but soon abandoned the idea of medical ractice.

In more recent times the presidential chair of the Geological Society has been occupied by William Babington (1756–1833), physician to Guy's Hospital, and by John Whittaker Hulke (1830–1895), surgeon to the Middlesex Hospital, to whom that Society awarded the highest prize in its gift, the Wollaston medal, founded by our former Fellow, the distinguished chemist and mineralogist of that name.

Physics and chemistry are the fundamental sciences upon which physiology and medicine rest, and throughout their history have been closely associated with medicine. Galileo Galilei (1564–1642), equally pre-eminent as astronomer and physicist, was a student of medicine when he watched the swing of the lamp in Pisa Cathedral, and so discovered the law of the pendulum. It was by his pulse that he timed the swing, and the first use which he made of his discovery was to construct an instrument to measure the frequency of its beats. The other outstanding physicist of the sixteenth century was a Fellow, and sometime President of this College, William Gilbert (1540–1603), founder of the science of magnetism, who recognised the earth's magnetic properties. Of him Dryden wrote:

> "Gilbert shall live till loadstones cease to draw,
> Or British fleets the boundless ocean awe."

This College can also claim amongst its Fellows one of the most brilliant men of science whom our country has produced, Thomas Young (1773–1829), whose discoveries in optics, and especially that of the interference of light, went far to establish the undulatory theory. He was the first to detect astigmatism, and threw much light upon the mechanism of the eye and on colour-vision. He was a great linguist also, and by his work on the Rosetta stone aided materially the interpretation of the demotic text thereof. Yet he found time to hold the office of physician to St. George's Hospital, and to practise medicine.

Amongst other great medical physicists I may recall the name of Luigi Galvani (1737–1798), physician and anatomist, who was led to the discovery of current electricity by his investigations of the electric organs of certain fishes; William Charles Wells (1757–1817), who solved the problem of dew; Julius Mayer, physician of Heilbronn, to whom is due some of the credit of the determination of the mechanical equivalent of heat, and, in our own time, Hermann von Helmholz.

There was a time, towards the end of the seventeenth century, when a dominant position in medical thought was held by a group of so-called iatro-physicists, who, influenced by the work of Galileo and his followers, and by the views on physiological problems, of two great mathematicians, Descartes (1596–1650) and Borelli (1608–1679), endeavoured, but with far less competence, to extend them to all physiological processes by the supposed action of forces upon particles of various shapes and sizes. Like the iatro-chemists, whom they superseded, they went too far, had their day, and passed. In the true line of succession from Borelli, on the other hand, was James Jurin (1684–1750), a Fellow of this College and physician to Guy's Hospital. He was an eminent mathematician and physicist, whose aim it was to make physiology an exact science.

With chemistry the links are even closer. The alchemist, who sought to prepare the elixir of life, had kindred aims to those of the physician. Later, in the period of the iatro-chemists, followers of Paracelsus, van Helmont and Sylvius, medicine was regarded as a mere branch of chemistry, and physiology as a study of fermentations. Curiously like, and yet quite unlike the physiology of to-day. A more practical tie between chemistry and medicine was provided by the chemical side of pharmacy and the study of poisons.

It was not until the seventeenth century that chemistry began to be studied as a pure science, in the days of Robert Boyle, upon whom, as an appropriate recognition, Oxford bestowed the degree of Doctor of Medicine, and others who, like him, were actuated by a desire to know the nature and composition of things. At Oxford, the second holder of the short-lived Ashmolean Professorship of Chemistry, Edward Hannes (d. 1710), was a physician; in the early years of the eighteenth century lectures on chemistry were given by John Freind (1675–1728), a Fellow of our College and Harveian Orator, and by several other medical graduates; and the first holder of the Aldrichian chair, founded in 1803, was John Kidd, afterwards Regius Professor of Medicine.

In the earlier days a knowledge of practical chemistry was only to be acquired by students in the shops of apothecaries, and as a scientific training this left much to be desired. It was Vauquelin (1763–1829) who first organised courses of instruction in his own laboratory in Paris, and this method was followed by Thenard (1777–1857) and Gay Lussac (1763–1829) and greatly extended by Liebig (1803–1873). Ernst von Meyer states that the laboratory of Thomas Thomson (1773–1852), a Doctor of Medicine of Edinburgh and Professor of Chemistry in Glasgow, was the first to provide practical teaching in Great Britain, and it was not until 1845 that the College of Chemistry was established in London, with A. W. Hofmann as its director.

The list of physician chemists is a long one, and only a few of the most eminent can be mentioned. First may be recalled John Mayow (1643–1675), one of the greatest of them all. Mayow stands high on the roll of physiologists, as well as of chemists. From the point which he reached only one step remained to the complete explanation of respiration and combustion, and but for his too early death, the discovery of oxygen would almost certainly have been antedated by a century, and phlogiston would never have been heard of. Although a Doctor of Civil Law, Mayow practised medicine at Bath. A contemporary of Mayow was our Fellow Thomas Willis (1621–1675), whose work upon the anatomy of the brain is commemorated by the circle of arteries which bears his name. But Willis was also no mean chemist, and to him we owe the discovery of glycosuria. Mention must be made of Friedrich Hofmann of Halle (1660–1742), a contemporary of Boerhaave, and of the illustrious Herman Boerhaave (1668–1738) himself, whose treatise on chemistry was long the best text-book of the subject. Yet eminent as Boerhaave was as a chemist, it was as a physician and Professor of Medicine that he was pre-eminent, and it was during his tenure of its chair of physic that Leyden, as a school of medicine, reached its zenith. Cullen (1710–1790), Joseph Black (1728–1799) the discoverer of latent heat, and Wöhler (1800–1882) who, by his synthesis of urea, bridged the imaginary gap between inorganic and organic compounds, were all members of our profession who made notable contributions to chemical knowledge. It was a Professor of Medicine of Halle, Georg Ernst Stahl (1660–1734), who propounded the strange theory of phlogiston, which, like the old man of the sea, clung around the neck of chemistry and obsessed chemists for more than a century. This hypothesis, which presented an inverted picture of the truth, like a glove turned inside out, was upheld by men of the highest ability, and by none more tenaciously than by such men as Priestley and Scheele, whose own researches were knocking away the props upon which it rested. The great Swedish man of science, Berzelius (1779–1848), the foremost chemist of his time, and the inventor of our system of chemical symbols and formulæ, was a Doctor, and for a time a Professor, of Medicine; and it was by his friend Alexander Marcet, a Fellow of this College, and one whose services to biochemistry are not sufficiently remembered, that Berzelius was led to illustrate his lectures by experiments.

Two more physician chemists may complete our series, William Hyde Wollaston (1766–1828), a Fellow of this College, a most eminent man of science, whose contributions extend over physiology and pathology, mineralogy, optics, botany, and above all chemistry, and William Prout (1785–1850). Wollaston discovered the malleability of platinum, a property of great value to chemists and physicists alike, detected cystin in urinary calculi, and invented the camera lucida. Prout was one of the founders of biochemistry, and discoverer of the hydrochloric acid in the gastric juice. His much discussed hypothesis, usually spoken of as "Prout's law," that the atomic weights of other elements are multiples of that of hydrogen, and that hydrogen is the basal substance from which all the other elements are formed, has long served as a potent stimulus to observation and research, and now, in a sense, is coming to its own.

In these later days the ties between medicine and chemistry are being knit more closely than ever before. Most drugs of recent introduction are, like aspirin, by-products of the gas-works or dye factory, or like salvarsan and its allies, synthetic products of the laboratory. But far more important to the progress of medical knowledge is the light which is being thrown, by the rapid advance of biochemistry, upon the problems of metabolism and chemical structure of the body.

The history of other sciences tells a like story. Almost all the early botanists were medical men, and the chief stimulus to the study of botany was the search for useful drugs. This is true even of classical times, the days of Theophrastus and of Dioscorides. The early scientists were, with few exceptions such as Archimedes, observers rather than experimenters, and the mere differentiation and naming of genera and species, a branch of science which dates back to the Garden of Eden, and of which that great naturalist, Linnæus, was a brilliant exponent, afforded an immense field of work. Of the "Materia Medica" of Dioscorides Charles Singer writes:—"Its history has shown it to be one of the most influential botanical treatises ever penned. It provided most of the little botanical knowledge which reached the middle ages. It furnished the chief stimulus to botanical research at the time of the renaissance." In the fifteenth and following centuries a long line of medical botanists carried on the tradition, including Brunfels (1484–1534), Fuchs (1501–1566), Bock (1498–1554), and Gesner (1516–1565) the most learned naturalist of his century, botanist, zoologist, artist and professor of Greek, who died of plague whilst faithfully carrying out his duty, as town physician at Zurich, during an epidemic of that malady.

But to quote Miall once more:—"It was generally believed that for every ill that flesh is heir to, Nature had designated some plant as the appropriate cure," and again "Some believed that Providence had caused particular plants to grow in those districts where the diseases which they cure are prevalent." Can it be denied that such tenets are held by millions at the present day?

The high distinction of having initiated the study of vegetable anatomy and physiology, those higher branches of botany, is shared by two men of the seventeenth century, both of whom were physicians. One of them, Nehemiah Grew (1641–1712), we may proudly claim as a Fellow of our College. He it was who first recognised the sexes of plants and the functions of the stamens, but he himself gives some of the credit for this to our former President, Thomas Millington. Of Grew, Hallam wrote that "no man, perhaps, who created a science has carried it farther," but he must share the renown with no less a colleague than Marcello Malpighi (1628–1694), in whose splendid record the study of plant anatomy takes but a minor place. A professor of medicine, zoologist and botanist, founder of the science of embryology, elucidator of the structure of the lung, spleen and kidney, to Malpighi must be assigned very high rank amongst those who have contributed to the advancement of natural knowledge

On the other side, the greatest of systematic botanists, and founder of our system of nomenclature of plants and animals, Carl Linné, commonly called Linnæus (1707–1778) who has been said to have "found botany a chaos and left it a cosmos," was not only a Doctor of Medicine, but held the office of Physician to the Swedish Navy, and practised in Stockholm for a time.

The ties between medicine and zoology are less obvious, for the search for animal drugs can hardly have led anyone to the study of natural history. But the transition from human to comparative anatomy is easy, and there have been medical zoologists from early times. In the sixteenth century we find the names of Rondelet (1507–1566), Belon (1517–1564), Conrad Gesner once more, and of our own former President Edward Wotton (1492–1555), whose work, "De Differentiis Animalium," gained for him an European reputation, but is marked rather by erudition than by originality of outlook and observation. In the seventeeth century there lived and worked Malpighi, whose chief contribution to zoology was a very complete study of the anatomy of the silkworm, Swammerdam (1637–1680), the Dutch microscopist who first observed the red corpuscles of the blood, and two Fellows of this College, Martin Lister (1638–1712) a man with wide interests and a special bent for the study of marine and freshwater molluscs, and Edward Tyson (1650–1708), the author of monographs upon the chimpanzee, porpoise, opossum and rattlesnake, and who first described the patterns upon the finger-tips.

In recent times, we may claim Richard Owen (1804–1892) who was credited with the power of reconstructing an extinct monster from a single bone; and also one whose eloquent words still ring in the ears of some of us, the greatest of medical zoologists, Thomas Henry Huxley (1825–1895).

In reality, botany and zoology are far more closely allied to medicine than our fathers knew. Since most maladies are due to invasion of the body by lowly organisms, some animal and some vegetable, we need to approach the study of disease from the standpoint of the invaders which are ever trying to gain a foothold, as well as from that of the tissues which present the rôle of a culture-medium and offer all the resistance in their power. In that struggle, which is waged with varying fortunes, we physicians are the allies of our patients, whose own tissues play the chief part in the defence. In order that our aid should be as efficient as possible we need to know all that can be learned about the nature and habits of the invaders, and of the insects which are the other hosts of some of them; and the study of bacteria is a branch of botany, and that of protozoa of zoology.

At the renascence of the medical sciences it was in human anatomy that the first advances were made, and the new anatomy was based upon dissection of the human body. The pioneer of this advance was Andreas Vesalius (1514–1564). His work was carried on in Padua. Others had dissected the human body before him, in Alexandria and at a later time in Bologna, but the prevalent teaching of anatomy followed the text of Galen, and was based, almost wholly, upon dissections of monkeys and lower animals. From Vesalius dates the great period of the medical school of Padua, during which there taught there, after Vesalius, Fallopius (1523–1562), Fabricius of Aquapendente (1537–1619), Casserius (1561–1616), and Spigelius (1578–1625), men whose names are written large upon the organs and tissues of the body. To Padua also, despite the difficulties, discomforts and even dangers of travel in those times, came students from afar, and amongst them our own Thomas Linacre, John Caius and William Harvey. As Sir Clifford Allbutt justly said, in his notable Harveian Oration, delivered a quarter of a century ago:—"It was in Padua that medicine, long degraded and disguised, was now to prove her lineage as the mother of natural science, and the truth of the saying of Hippocrates, that to know the nature of man, one must know the nature of all things."

It is not necessary that I should dwell upon the share of medical men in the building up of modern physiology, for from Harvey onwards it has been almost entirely their work; but the day has passed in which physiology was regarded as the handmaid of medicine, and it has taken its proper place as a great independent science.

Morbid anatomy, as an adjunct to clinical medicine, dates back to the illustrious Morgagni (1682–1772), and so to Padua once more, and is intimately associated with the other great names of Albert von Haller (1708–1777) and Rudolph Virchow. Knowledge of the changes, both great and minute, wrought by disease in the organs and tissues is still as essential as ever in the training of the physician and surgeon, but morbid anatomy is no longer coextensive with pathology, and the pathology of to-day has entered upon entirely new fields. So, as we well know, modern pathology has rendered possible the destruction of the agents of disease, or of their insect hosts before they reach the body, the triumphant achievements of preventive medicine. Moreover, as the result of the study of immunity, the bacteriologist is teaching us how to apply Nature's own selective remedies in place of the cruder drugs of earlier days. At the same time, the pharmacologists are bringing to the test of scientific method the actions and uses of drugs which have long been used in an empirical way, and are able to explain the proved utility of some which owe their introduction into the pharmacopœia to superstition, or to some grotesque hypothesis.

So, from the foundations of chemistry, physics, and biology, through the lower stories of human anatomy and physiology, of pathology and pharmacology, we reach the attics once more, and come back to Hippocrates, to the bedside examination of the sick and injured. But, now that the foundations have been well and truly laid, the clinical medicine of to-day is able to advance on scientific lines, and the study of the abnormal can be based upon a knowledge of the normal.

All who have taken part in this work, all those heroes of science and medicine whose names have been mentioned, may rank as benefactors of this College, both those who were its Fellows and those who were not, and in commemorating them I may claim to have followed Harvey's first injunction.

It is natural, nay inevitable, that as medical science grows and advances, some of the workers in the field should elect to follow the path which leads through the laboratory, whereas to others the wards make a stronger appeal; and thus is taking place a differentiation of medical workers into distinct groups, and there is danger that the fission may go too far. The worker in the laboratory, wedded to his more exact methods, and distrustful of those with which the clinician is often compelled to be content, is apt to place his bedside colleague in a lower grade or caste than his own. He is apt to look too much at the disease and too little at the patient, and to forget how greatly the former is shaped by the reactions and idiosyncrasies of the latter.

We all know that a line of treatment resting upon a strictly rational basis may be useless or even harmful in an individual case. It would be nothing short of a calamity were all the best scientific workers who enter our profession to be diverted from its clinical side to laboratory investigation, for of no walk of life is it more true than of the practice of our art that "the multitude of the wise is the welfare of the world." From the ranks of the clinical workers have been drawn those who, in the past, have built up medical science. It was in the intervals of their clinical practice that such men as Harvey himself, William Gilbert, Nehemiah Grew, and Thomas Young carried out the researches which have made them for ever famous; and indeed, clinical medicine is itself essentially scientific.

But clinical medicine is an art as well as a science, and in the sick room many qualities are called for which are not essential in the laboratory. A man who is deeply imbued with the spirit of science may prove a very poor practitioner, whereas another, rich in common sense, sound knowledge, experience, and human sympathy, but to whom abstract science makes little appeal, may make a very good one. Tact and equanimity, courage and restraint, patience with fads and sympathy with grief, diagnostic skill and manual dexterity are qualities called for in the daily work of the practitioner of medicine or surgery. The marvel is that, on the scientific side, he has accomplished so much, not that he has failed to accomplish more. It ill becomes his colleagues in the laboratory to think slightingly of him.

Medicine, indeed, embraces a number of constituent sciences, and for the attainment of her beneficent aims, all her branches need to work together in mutual respect, amity, and concord; to bear in mind Harvey's third injunction to that effect, and his reminder that: "Concordiâ res parvæ crescunt, discordiâ magnæ dilabuntur."

Not only are the diagnostic methods which we employ in accord with the demands of science, but also, by the bedside study of signs and symptoms, and the recognition of the morbid anatomical changes with which they are associated, as also by the observation of the effects of surgical removal or gunshot injury of parts, very notable contributions to physiology have been made.

Consider, for a moment, how our knowledge of the functions of the endocrine glands has been obtained. The acumen and care in observation of that splendid clinician Addison threw the first ray of light upon the subject, and removed the adrenal glands from the realm of mystery into that of observed fact. The gradual accumulation of facts concerning exophthalmic goitre, Gull's discovery of myxœdema, Kocher's observations upon cachexia strumipriva, and the effects of thyroid treatment, provide a connected story of clinical work in medicine and surgery, which led up to a solution of the functions of the thyroid gland, and which had its practical outcome in the restoration to health of many sufferers from myxœdema, the rescue of many cretins from imbecility and arrest of growth, and the amelioration of the lot of many sufferers from Graves's disease. Again it was the recognition of acromegaly by Pierre Marie, the study of its symptoms and morbid anatomy, the recognition by Fröhlich of the syndrome which bears his name, and that of the other results of pituitary defect, together with the surgical results of Cushing and others, which led us to our knowledge of the functions of the hypophysis, knowledge which has been greatly extended by the experimental work of Schäfer. Moreover, what inklings we have of the functions of the pineal gland, and of the adrenal cortex, are mainly derived from clinical observations of patients with tumours of those structures.

The chance that an accidental gunshot wound left the French-Canadian Alexis St. Martin with a gastric fistula, and that the American army surgeon, Beaumont, under whose care he came, was able to take full advantage of the opportunity so afforded, of studying the secretion and action of the gastric juice, proved of the utmost value in the elucidation of the problems of digestion. And in these times many clinical devices, such as test-meals, duodenal soundings, and bismuth meals, are throwing yet further light upon physiological as well as pathological processes.

The knowledge acquired in recent years of the mechanism of the heart's action is a triumph of scientific clinical medicine. This work, which is so closely associated with the names of James Mackenzie, Thomas Lewis, Wenckebach, and Einthoven, has been gained mainly by the study of derangements of the heart's beat in man, by means of the polygraph and electro-cardiograph.

But perhaps the most striking examples of all are afforded by the work which has been done upon the nervous system. Bouillaud described clinical and pathological physiology as the sister of experimental physiology, and since the middle of the nineteenth century an immense amount of knowledge of the functions of the brain and spinal cord has been acquired by the labours of a band of brilliant investigators, many of whom are our own countrymen, and most were, or are, physicians or surgeons. Of these I may mention Hughlings Jackson and David Ferrier, Charles Beevor, Victor Horsley, and Henry Head in this country, and on the Continent, Hitzig, Erb, Westphal, and Pierre Marie. By their researches they have furthered the work of the pure physiologists, Sherrington, Gaskell, Langley, Gotch, and others.

As regard localisation, the first definite steps indicating that the brain does not function as a whole, but as a congeries of organs, was the localisation by Broca, of the motor speech centre, in 1861, which was based upon the position of the local lesions in fatal cases of aphasia, and Hughlings Jackson's study of convulsions due to cortical lesions. These observations served as stimuli and pointed a way which was followed by many other observers, but by a not unfamiliar irony of things the assignment of a speech centre to the convolution of Broca no longer meets with acceptance.

Lastly may be cited the work of Head upon the seats of pain due to visceral lesions, and upon epicritic and protopathic sensations. It is clear that clinical observation is the royal road to the study of many kinds of sensory disturbance, in which an intelligent subject who can describe his sensations is needed, and in some instances the investigators have controlled their clinical observations by experiments upon themselves.

The examples quoted show that apart from the study of disease in bulk, and by statistical methods, there is also much to be learnt from the detailed study of individual cases.

In a letter which Harvey wrote, only six weeks before his death, to a Dutch physician who had sent him an unusual specimen, occurs the following passage: "It is even so—Nature is nowhere accustomed more openly to display her secret mysteries than in cases where she shows traces of her workings apart from the beaten path; nor is there any better way to advance the proper practice of medicine than to give our minds to the discovery of the usual law of Nature, by careful investigation of cases of rarer forms of disease. For it has been found, in almost all things, that what they contain of useful or applicable is hardly perceived unless we are deprived of them, or they become deranged in some way."

These words, as true to-day as when they were written, are full of encouragement for those of us for whom the study of Nature's experiments and mistakes has a special attraction. The structural malformation, or the hereditary and inborn departure from the normal of metabolism, although unimportant from the practical standpoint, may throw a ray of light into some dark place of embryology or biochemistry; and not a few of the rare maladies, such as chloroma, polycythæmia vera, sulphæmoglobinæmia, and the disease of which Bence-Jones albuminuria is a sign, offer fascinating and still unsolved problems of physiology and pathology.

Obviously clinical medicine presents immense fields of scientific research, and those who cultivate them have the added satisfaction of knowing that every advance of medical science will, sooner or later, bring in its train some forward movement of the healing art.

So, as we trace the history of natural science down through the centuries, we are confronted, at every stage, by the influence of medicine upon its progress. The desire to alleviate human suffering, to repair the ravages of disease, and to mend the broken part, has served as a powerful stimulus to observation and experimental work. It soon became obvious to the would-be healers that to understand disease they must needs understand the healthy workings of the organism, and that pure science must precede applied. So, as Huxley said, medicine became the foster-mother of the sciences. But she became their schoolmistress also, and attracted to herself men whose scientific abilities would hardly have found an outlet in the other walks of life open to them in the earlier days, and them she not only taught, but supplied with means of livelihood whilst they pursued their chosen studies. Her part was rather that of a mother than of a foster-mother. They, in their turn, repaid her care by laying firm foundations upon which a rational healing art could be built up, and, as we have seen, not a few of them achieved epoch-making results in sciences outside the range of medicine.

Thus it has come about that immense, and indeed incalculable, as is the debt of medicine to the pure sciences, the debt of science to medicine is hardly if at all less great. But these mutual obligations are but internal debts, and the fact that medicine, in its widest sense, is merely a branch of natural science was recognised even by Aristotle who, at the end of his work on respiration, wrote as follows:—

> "Our discussion of life and death and kindred topics is now practically complete. But health and disease also claim the attention of the scientist and not merely the physician, in so far as an account of their causes is concerned. The extent to which these two differ, and investigate diverse provinces must not escape us, since facts show that their enquiries are, to a certain extent at least, conterminous. For physicians of culture and refinement make some mention of natural science, and claim to derive their principles from it, while the most accomplished investigators into nature generally push their studies so far as to conclude with an account of medical principles."

Yet, as Huxley pointed out, "It is a peculiarity of the physical sciences that they are independent in proportion as they are imperfect; and it is only as they advance that the bonds which unite them become apparent." That this is so is far more obvious to-day than when these words were spoken more than 40 years ago. For as we gain more knowledge innumerable fresh links are brought to light; and the unity of natural science is daily being revealed more clearly as the boundaries of its several branches fade and become indistinct.

Few will any longer question the view that physiology is merely the chemistry and physics of living things. Physics has captured the structure of the atom, is absorbing chemistry into itself, and is becoming revealed as the great fundamental science, of which all the others are but branches. In this great complex of interlocked studies those which we class together under the comprehensive name of medicine have their allotted places, and advance in any one branch forwards the progress of the whole. To take our part in this progress is alike our privilege and our obligation as members of the great band of seekers after natural knowledge.

Upon the ceiling of the cloister of the University of Padua there are painted "stemmata" which record the sojourn there of many students who were councillors of their several "Nations," and amongst them are two which bear the name of Gulielmus Harveus, Anglus. Some of the designs are heraldic, but Harvey's is symbolic, nay prophetic. A right arm and hand holds up a caduceus, in which, in place of a lifeless staff, the twin serpents are entwined around a lighted candle which throws out beams in all directions. What more fitting emblem could have been devised? And yet these stemmata were painted when Harvey's work was scarce begun, and when he was still a member of the student body. To "search and study out the secrets of Nature by way of experiment" was his own way of life, and it is my duty to obey his injunction, and to exhort our younger brethren in the College to tread the path in which he led the way, and to see to it that in their hands the flame which Harvey lit shall burn as brightly as in Harvey's day.

Introductory Lecture
ON
PSYCHO-PHYSICAL INTERACTION.

Delivered at the Tavistock Clinic on Oct. 13th, 1924,

BY H. CRICHTON-MILLER, M.A., M.D. EDIN.,
HON. DIRECTOR, TAVISTOCK CLINIC FOR FUNCTIONAL NERVE CASES.

A COURSE of lectures on psychotherapy may well be introduced by a consideration of the interaction between mind and body. I find that both students and practitioners of medicine attend these lectures with views on this subject that are, to say the least, indefinite. The fundamental trouble is that our medical training tends to make us *causalists*—that is to say, we acquire a habit of labelling a clinical condition, and memorising a single cause for it. For instance, the picture of diphtheria is a clear-cut one, and it is satisfying to regard Löffler's bacillus as the causative agent. Asthma is a condition so simple to diagnose that we are generally saved the trouble by the patient's information. But when we talk of a cause, we find nothing specific, no satisfactory *causa causans* comparable to Löffler's bacillus. Every victim of asthma has his own views and theories as to causation. Rarely is it possible to correlate these with any of the views held by modern physicians. Frequently we are struck by the fact that anticipation and association constitute precipitating, or at least predisposing, factors. Now and again we come across what appears to be a definite and specific ætiology. For instance, a patient may state that he gets asthma if he eats egg or any article of diet containing the minutest fraction of egg. On testing his protein sensitivity to egg we find he reacts energetically. Here, then, is a case in which we approach a cause for a morbid state. But in general the ætiology of asthma is complex, and the more we study it the more we are forced to recognise that the clinical picture results not from a cause but from the conjunction of various conditions, and that these conditions need not all be physical, but may be some physical and some emotional in their nature. To study such a disease we must approach it from the standpoint of conditionalism. A woman who suffered from asthma whenever she was at the seaside discovered to her surprise during her first pregnancy that she was unaffected, and this observation was confirmed during subsequent pregnancies. Hence her asthma, if it was caused by an atmospheric factor, was also influenced by a metabolic factor involved in pregnancy. Again, I have said that a disease such as asthma may be conditioned not only by different organic factors but also by emotional factors. For proof of this we have but to look to the various forms of faith-healing, suggestion, and auto-suggestion. All of these can claim with good authority permanent cures of cases of asthma. Most general practitioners have come across cases of this disease conditioned by all sorts of fears, preconceptions, and superstitions. I submit, then, that no efficient treatment of asthma can be based upon any preconceived theory of cause and effect. We must study the conditions which determine attacks, and we must address ourselves to the treatment of these conditions in order of their therapeutic accessibility.

THE LIMITATIONS OF NEUROLOGICAL LOCALISATION.

Our neurological friends have for many years laid great stress on localisation, and by localisation astonishing and dramatic cures have been and are being wrought. But localisation frequently affords little or no help in therapeutics. It is right and proper that we should all know that paralysis agitans is essentially the result of degeneration of the posterior elements of the basal ganglia. But the knowledge brings with it no clear therapeutic inspiration. I would almost go the length of saying that to some medical minds—of second-rate calibre, of course—the knowledge may lead to a therapeutic pessimism even greater than is called for. Is it not possible that sometimes our neurological localisation impedes our searching as conscientiously as we might for sources of degeneration, such as systemic infections? If the sufferer from paralysis agitans have an intestinal infection of long standing, it is clearly more important to him that the organism be isolated than that the neural degeneration be localised.

Ménière's disease is another example. I have seen a case so labelled that had undergone five operations—two on the mastoid and three on the labyrinth. When all the semicircular canals had been obliterated the symptoms remained apparently unaffected. Now I am perfectly prepared to believe that this patient originally suffered from organic disorder of the ear. I had no opportunity of judging as the patient was brought to me only after the failure of these somewhat heroic methods. I can, however, make two statements about this case: (1) her transverse colon, which was removed by an eminent surgeon and is to be seen in a certain University museum, measured 19 inches in diameter (the patient was an ill-developed girl of 23); (2) psychologically she was a complete case of the Freudian Electra complex down to the last detail.

I imagine that surgeons of the Lane school would have been very ready to attribute the vertigo to intestinal toxæmia. I am certain that many psychoanalysts would have put it down to conversion hysteria, and we know that the otologists (for several were involved) attributed the vertigo to labyrinthitis. From the analytical standpoint there is no necessity to admit either of these physical factors. I mean by that that the psychological picture was complete; that the vertigo and its incidence fulfilled the defence function of a psychoneurosis, and that it was possible in the subsequent analysis to associate the illness and its various manifestations with the patient's morbid reactions to her situation. Her mind was in an exceedingly morbid condition—only comparable to the state of her colon. And the proof remains that after her colon had been transferred from the abdomen to the museum, and after her ear had been operated on five times she continued to complain of vertigo.

We may say with a certain degree of safety that no one of these factors was the cause of the vertigo. We must assume, I think, that all three were conditioning factors. (In point of fact I believe there were others which need not be referred to.) The function of the psychotherapist is, I take it, to influence these conditions in so far as he can do so through the mind. It is not his business to extirpate semicircular canals nor to remove a distended colon. On the other hand, I conceive it to be very much his affair to assess as far as possible the relative importance of the ætiological conditions. It is possible, but perhaps not probable, that the otologists might have spared a canal or two, had they been in possession of the data obtained from subsequent analysis. It is also conceivable that the abdominal surgeon, had he possessed this information, might have given a somewhat less confident prognosis. But the human mind relapses very easily to causalism and only holds on to a conditionalist standpoint with difficulty. Whatever may be thought and said in other departments of medicine let the psychotherapist, before all his colleagues, maintain a broad conditionalist outlook, for there is nothing that has more militated against the popularity of our work than the narrow views of psychogenesis that have been enunciated by some. The more experience I have in this field, the more am I inclined to say that very few diseases are caused solely by a mental factor, and that there are few diseases into which a mental factor may not enter. We often hear the taunt, "Can Christian Science cure a broken leg?" Of course the answer is in the negative, and yet it seems to me conceivable that acute anxiety may have in certain cases such a far-reaching effect on the circulation as to influence, albeit in a minimal degree, the process of repair.

One of the best examples of conditional ætiology is probably dementia præcox. The factor of gonadal inadequacy has been clearly demonstrated by Sir Frederick Mott's researches. Jung and other analysts have shown the constant presence of a conflict over authority. These theories may seem mutually contradictory, but if we regard them from the point of view of conditionalists, we see in them factors which by their conjunction may determine the familiar psychosis. It is clear that the adolescent, as he passes into maturity, regards the challenge of life in relation to two factors. The first is the menacing character of that challenge, and the second is the biological sense of adequacy within himself. If a boy is always assured by his father that he will never succeed in life if he does not mend his ways, he is apt to conceive of life as a very arduous and exacting proposition. If he feels the potency of a normal young adult male, he will face this and make good. But if the endocrine factor is defective he will retreat from life, and if it is very defective he will still retreat from it, though the prospect of manhood has been presented to him in perfectly suitable terms. If a motor-car stops on a hill we may say that the engine is weak or the hill is steep. This is the attitude of the causalist. The conditionalist says that for such a hill the engine was too weak, or for such an engine the hill was too steep.

THE CONNEXION BETWEEN DUCTLESS GLANDS AND MENTAL PROCESSES.

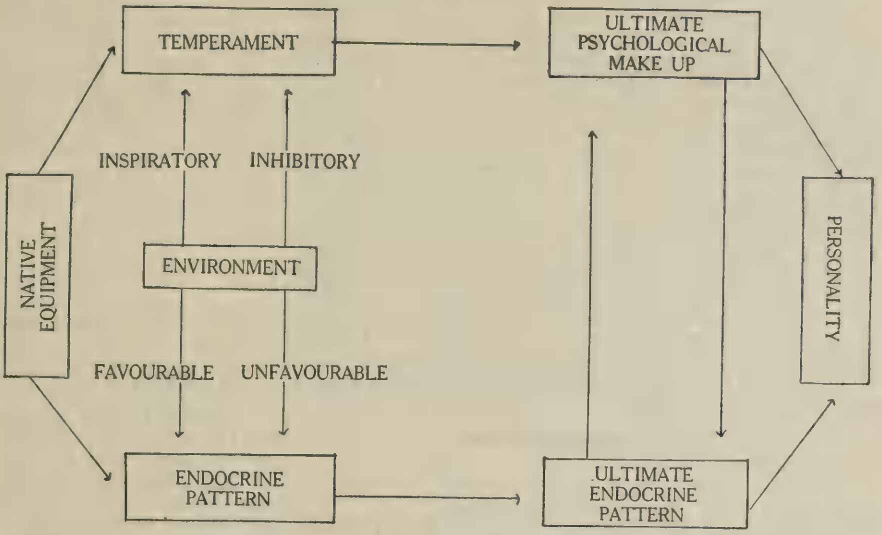
This example brings us to the important question of the connexion between the ductless glands and mental processes. There are certain scientific circles in which it is fashionable nowadays to decry organotherapy. The usual high-brow formula is, "We have not a trace of evidence that any endocrine substance taken by the mouth is assimilated, with the sole exception of thyroid." It is very natural. The commercial drug houses have exploited organotherapy with more zeal than wisdom. The subject is intensely complex, and it is always easy for the scientist to attribute to suggestion any therapeutic efficacy that may be claimed for organotherapy.

As I am not an endocrinologist I hold no brief for organotherapy, but I advise you very strongly to read all the best literature you can get on this subject—experiment continually, and formulate your own conclusions as to efficacy or otherwise. The organotherapy of to-day may be a very feeble affair, but I believe very firmly in the organotherapy of to-morrow, and that is going to be based largely on honest clinical observation. There is nothing more dramatic in the whole of medicine than the dissipation of the depression of a subthyroidic patient by the administration of thyroid extract. That particular value of thyroid was not discovered in a laboratory. I believe there is a range of subtle subjective phenomena that depend on endocrine deficiencies or disequilibria and that one day we shall be able to treat them by an improved organotherapy. I hope I have said enough to make you realise that the practical psychotherapist must always have an eye open to the patient's endocrine situation. In other words, the endocrine factor constitutes a condition of many abnormal mental states.

SYSTEMIC INFECTION.

Another condition which the psychotherapist must be alive to is that of systemic infection. I see a good many cases who are sent by their doctors as being "organically sound." In some cases their mere appearance belies this statement. In other cases a blood count reveals a serious lymphocytosis. In others, again, there is found to be a very low basal metabolic rate. In one case I recall this phrase was applied to a man whose cerebro-spinal fluid gave a very positive Wassermann reaction. It is, no doubt, a matter of terminology, but I should not feel inclined to describe any such cases as "organically sound."

Now the psychotherapist needs to consider the condition of toxæmia more than most physicians for this reason. A large number of our patients are people who temperamentally react to toxic absorption first of all on the psychic plane. They may develop irritability, lassitude, or phobiæ. They repeat the familiar formula, "It's all my nerves, doctor." Their family physician regards them as run down, and when the usual tonics fail to effect a cure he begins to suspect them of being hysterical, and casts around for some wastepaper basket to which he may consign such unrewarding clinical material. If such a case had reacted to the systemic infection by developing arthritic changes, the family physician would no doubt have instituted a careful search for a focus of infection. Tonsils and sinuses, teeth and intestines would probably have been thought of with a view to radical treatment. But if the symptoms are mere "nerves," or even a threatening psychosis, focal infection does not occur as a possible ætiological factor. Recently I was consulted about a young married woman who had developed mental symptoms shortly after her first confinement. She was in a private asylum. I communicated with the superintendent and asked for information. I was told that she had a bad heredity, and was holding her own. I asked if there was any evidence of a toxic factor, and suggested that a blood count might possibly throw some light on the situation. The only result was that the husband was told that the examination I suggested could not be carried out, and that he might remove his wife if he wished me to treat her. Now I perfectly appreciate the superintendent's emphasis on heredity, but we must remember that heredity is a factor that influences prognosis, but does not affect treatment. In mental cases a bad heredity should stimulate us therapeutically—it too often tends to paralyse us. I think the superintendent had allowed himself to be paralysed by the idea that a puerperal psychosis was just what one would expect in a woman with such a heredity. But why not investigate the question of infection? Surely it is not too much to ask for a blood count? Furthermore, it is obvious that in all puerperal conditions the question of endocrine disequilibrium necessarily arises, seeing that parturition involves the greatest physiological upheaval to which the endocrine system can be subjected.



HOW PERSONALITY IS BUILT UP.

I have found it useful in studying personality to think of the factors that have contributed to its final form according to the accompanying schema. By native equipment I mean the things that we start with, such as musical talent, red hair, and a sense of humour. Red hair is no doubt attributable to something specific in our original endocrine pattern. Whether musical talent is associated with the endocrine system or not is an open question—many have claimed that it is so; and when it comes to a sense of humour, I only know that of all human characteristics this is the most essentially congenital one in that it appears to develop or not without any reference to environment.

Now our endocrine pattern is influenced by environmental factors, favourable or unfavourable. Thus a child may start life with an inherited potentiality of great stature, and owing to morbid influences the endocrine pattern may undergo change, and he may reach maturity with only stunted growth. Similarly, a child may start life with a well-balanced thyroid function, but when puberty supervenes the influence of the developing gonads upon the adrenals and on the sympathetic system may well result in an over-activity of the thyroid which we are accustomed to observe clinically, especially in girls. We are accustomed to think of the mental effects of hypertrophied tonsils and adenoids upon the child, but we are apt to forget that this result is produced entirely through the endocrine system. Chronic toxæmia affects first the thyroid and then the adrenals in such a way as to produce the familiar heaviness of such cases.

Thus we reach our ultimate endocrine pattern. Throughout life the endocrine system is subject to continual alteration of equilibrium of a physiological character, and throughout life it is exposed to toxic influences of one kind or another. Our personality at any given moment is what it is, partly because our endocrine pattern has undergone the changes which it has undergone. One woman is stout and cheerful because she has had five children, and the balance between her thyroid and ovarian hormones causes her to be so. This man is dull, irritable, and is losing initiative because an undiscovered abscess at the root of a molar has been slowly poisoning his thyroid for months, if not years. Every physician recognises that chronic constipation causes a multitude of troubles, both physical and mental, but we often fail to recognise that these morbid results can be interpreted in terms of adrenal deficiency.

Turning now to the temperamental factors, just as physiologic and pathologic factors constantly influence the endocrine pattern, so temperamental factors are subject to environmental influences of a psychic character. A child may be born with the possibility of a good memory, but his upbringing may do nothing to develop that memory, whereas another child with less possibility may be so trained as to develop to the full his power of memory. One child with excellent mathematical possibilities may go through life with them undeveloped, while another, no more richly endowed, becomes a Senior Wrangler.

Now the point we have to study as psychotherapists is the two-fold basis of personality—what I have called psychological make-up and endocrine pattern. I have tried to indicate some ways in which these attain their ultimate forms. Both contribute to personality, and it is useless to study the behaviour and reactions of an individual solely in psychological terms—still less in neurological terms. A depression which manifests itself after influenza is not a condition to be approached from the psychical point of view. Everyone will agree with this statement, and yet it may be paraphrased thus: "In so far as personality at any given moment is based upon the psychological make-up and the endocrine pattern of that moment, it is necessary to treat abnormalities of reaction from the psychological or the endocrine angle, according to which appears to be affected."

Thus, to go back to the question of dementia præcox. If there be a way to ensure gonad stimulation, it should certainly be used in conjunction with such psychological methods as are best calculated to overcome the patient's conflict over authority. So again, take the familiar disturbances of the climacteric. We know enough to realise that there are very definite psychological factors, and our success in treating these cases will depend upon our skill in both fields of therapy.

A great deal of dissension amongst doctors over psychotherapy may be traced to the fact that so few of us have successfully developed binocular vision. It behoves us as psychotherapists to develop this vision to the fullest extent possible, so that we may be able to approach every case with an open mind ready to accept whatever conclusions we may arrive at as to its ætiology, be the factors physical or mental. In connexion with the subject of this lecture the following books are worth reading: "The Sympathetic Nervous System," by Langdon Brown; "The Defective Delinquent and Insane," by Henry A. Cotton; "The Glands Regulating Personality," by Louis Bernan. The first-named is probably worth reading many times over. The second gives one a tremendous impression of the possibility of approaching mental disequilibrium from the point of view of toxic influences. The third is a very amusing, and to some extent suggestive book which should help us to think more clearly with regard to the endocrine system.

THE TREATMENT OF
MALIGNANT DISEASE OF THE TESTICLE.

By R. M. HANDFIELD-JONES, *M.C.*, M.S. Lond., F.R.C.S. Eng.,
ASSISTANT DIRECTOR, SURGICAL UNIT, ST. MARY'S HOSPITAL, LONDON.

"It must first be recognised that carcinoma, in the beginning, is an absolutely local disease."—Robert Abbe.*

In dealing with the treatment of malignant diseases of any organ there are certain well-recognised rules of technique which every surgeon attempts to fulfil. Briefly stated, they are that the primary growth is to be widely removed with its primary lymphatic field and all intervening tissue in one complete mass. The operations for removal of a carcinoma of the breast and of the colon provide excellent examples of the fulfilment of these rules of technique, which in these instances are universally carried out. For certain reasons, such as the inaccessibility of the lymphatic field, these rules have never been generally applied to the surgery of the testicle. In this country the balance of opinion is overwhelmingly in favour of a limited operation, and in most other countries the extensive radical operation finds only a limited measure of support. Occasional spasmodic efforts have been made to popularise the extensive procedure, but nowhere have they succeeded, with the one possible exception of the French school. Even there, so distinguished a genito-urinary surgeon as Marion has declared against it, and in America the great exponent—Hinman—is not followed to any marked extent. In this country the degree of unanimity in favour of conservative measures is somewhat surprising, but nevertheless there is a certain limited demand for heroic measures, and it appears advisable that both methods should be described and subjected to close criticism before a definite pronouncement can be made upon their respective merits.

Lymphatic Drainage of the Testicle.

The drainage of any organ is of paramount importance when surgical procedures are to be planned, for it is the lymphatic distribution which determines the extent of the operative field. This point is of unusual importance in the case of testicular tumours, as I have already foreshadowed. I have, therefore, carried out some injection experiments of the testicular lymphatics in the post-mortem room on bodies of varying ages. The experiments were done on much the same lines as those of Jamieson and Dobson,[1] in 1910, and they give very similar results. These observers have come to be regarded as the leading English authorities on many areas of lymphatic drainage, and their tabulated results are worth quoting (Table I.).

Table I.—*Jamieson and Dobson's Results.*

No. of expt.	To right of I.V.C.	Front of I.V.C.	Between aorta and I.V.C.	Front of aorta.		Left of aorta.
1	0	1	1	0	0	1
2	0	1	2	0	3	2
3	0	1	2	1	0	2
4	0	1	2	2	2	3
5	0	0	3	2	Not injected.	
6	0	1	1	0	2	1
7	1	0	3	0	0	1
8	0	0	2	1	Not injected.	
9	0	0	2	0	0	1
10	0	0	1	1	Not injected.	
		Right side.			Left side.	

All cases were full-time fœtuses.
Figures refer to the number of glands injected.

In two of their cases an injected gland was found on the right side of the pelvic brim. Those injected on the right side were on the level of the lower pole of the right kidney, and those on the left were in close relationship to the origin of the inferior mesenteric artery and from it down to the bifurcation of the aorta. These were all glands of the primary lymphatic field, but the injection fluid passed quite readily into the glands around the origin of the superior mesenteric and of the cœliac axis arteries, across to the glands on the opposite side, and downward to the external iliac group.

My own experiments were made with a saturated solution of methylene-blue injected into the body of the testicle. The fluid could be seen mounting upwards and reaching the glands. All the injections were done in the presence of several observers, all of whom were satisfied that the vessels injected were lymphatics, and that the fluid in them was undoubtedly the injection fluid (Table II.).

Table II.—*Results.*

No. of expt.	Age.	Right ext. iliac.	Right of I.V.C.	Front of I.V.C.	Between I.V.C. and aorta	Front of aorta		Left of aorta
1	Full time fœtus	1	0	1	1	0	2	1
2	,,	0	0	1	2	0	1	1
3	56	1	0	1	2	0	0	1
4	14	0	0	1	2	0	1	2
5	12	1	1	1	3	0	2	1
6	9	0	0	2	2	0	1	2
			Right side.				Left side.	

It will be noticed that in both sets of experiments a high proportion of the glands on the right side lie either in front of the inferior vena cava or between it and the aorta. The latter group lie deeply in the groove between these vessels. Those on the left side are intimately related to the inferior mesenteric artery. In two of my experiments a vessel was injected which as far as I know has not been described previously. It occurred on the right side in each case, and left the cord with the vas deferens, with which it did not keep in close contact, but ran parallel to it at a higher level, and ended in the prostatic plexus.

---

* Keen's Surgery, vol. iv., p. 158.

Simple Orchidectomy.

An incision is made one inch above and parallel to Poupart's ligament, and corresponds in length to the inguinal canal with a prolongation of one or two inches towards the scrotum. The aponeurosis of the external oblique muscle is divided from the external ring to the level of the internal ring. The whole cord is now dissected free and lifted from its bed, and the arching fibres of the internal oblique muscle being retracted upwards and outwards, it is traced to the internal ring. Two heavy crushing clamps are now applied to the cord, one at the ring and the other just distal to the first. The intervening tissue is now divided with the Pacquelin cautery, the proximal stump being then ligated and allowed to retract. It must be understood that the testicle still lies undisturbed in the scrotum, this being a point of technique I wish particularly to emphasise for premature handling before division of the cord tends to encourage lymphatic embolism. The testicle is now freed from its areolar attachments in the scrotum, and is delivered into the wound by gentle traction on the cord and pressure from below. It is now free and can be removed with the cord attached still clamped to prevent any malignant seeding of the wound. The aponeurosis of the external oblique is repaired, any bleeding points ligated, and the wound closed without drainage. The operative mortality is non-existent, convalescence is rapid, and the patient is allowed to walk on the twelfth day.

It is not necessary to remove any part of the scrotum in the ordinary way, but in those cases in which the growth has spread into the scrotal skin it may be considered right to do a palliative operation to relieve the patient of the fungating mass. There are many cases of superficial carcinoma which are really inoperable—e.g., those of the breast fungating through the skin, filthy malignant ulcers of the tongue—but in which the patient's general condition and especially his or her comfort is greatly improved by some palliative procedure. In such cases the testicle and its half of the scrotum are removed by a racquet incision, the handle of which corresponds to the usual inguinal incision, and the racquet is planned to suit the need of each individual case.

The Radical Operation.

In that I have never performed this operation, it follows that this account is based on the writing of others. The most recent and the most lucid exposition comes from Hinman,[2] and his technique is here outlined:—

Stage 1. Division of the Cord at the Internal Ring.—This step is exactly the same as that already described under simple orchidectomy, with one exception. Before severing the cord the vas is isolated at the ring, clamped, and divided separably, the rest of the cord being dealt with as before.

Stage 2. The Lymphatic Attack (operation on right side described).—The incision is now continued in an upward direction to the tip of the eleventh costal cartilage. It is carried through the muscles down to the peritoneum, which is then pushed inwards by gauze dissection, care being taken to strip the ureter and spermatic vessels, thus leaving them on the psoas major muscle. Beginning at the clamped end of the cord, the dissection is carried upwards and inwards until the spermatic vessels and lymphatics are cleared up to the inferior vena cava. The artery and vein are clamped and divided high up. The glands are then dissected with great care from the surface of the vena cava and from the groove between it and the aorta. The mass is now free and is removed.

Stage 3. Removal of the Vas.—Attention is now turned to the vas, the pelvic peritoneum being stripped up from the lateral wall. The vas is traced to the neighbourhood of the bladder, where it is divided wth the cautery.

Stage 4. Removal of the Testicle.—The final stages are as described under the simple operation, but a drain of rubber tissue must be inserted in the area of retro-peritoneal dissection for 24 hours. The incision is closed with care in layers.

Case for the Simple Operation.

It has been stated that the radical operation is not generally practised, and I have already indicated my opposition to it. It is obvious that very strong reasons must be brought forward to allow the abandonment of all the usual laws of the treatment of malignant tumours, and to set the seal of general approbation on a limited operation. Certain aspects of this unusual problem must be criticised separately.

1. *Feasibility of Complete Removal of the Primary Lymphatic Field.*—If the radical operation is to be justified, it must be proved that it is within the realms of surgical possibility to remove completely the primary lymphatic field without grave injury to vital structures. Jamieson and Dobson's description, which is supported by my own injection experiments, shows quite clearly that on the right side the glands primarily involved lie on the anterior surface of the inferior vena cava and in the groove between it and the aorta; and the dissection must extend from the level of the renal vein to the termination of the common iliac artery. On the left side the glands affected will lie to the left of, and on the anterior surface of the aorta, and bear an intimate relationship to the origin of the inferior mesenteric artery, and the extent of the dissection is as wide as that on the right. Further, the spermatic vessels and the testicular lymphatics are fairly firmly attached to the posterior surface of the peritoneum, and when the latter is pushed inwards during the operation the vascular lymphatic chain has to be dissected off the peritoneum. In so doing there is considerable danger of rupturing the fragile lymphatics and so seeding the wound with malignant cells if present.

It does not need a long memory on the part of any surgeon to picture the difficulties encountered in stripping carcinomatous glands off the internal jugular or the axillary veins. These veins can, however, be ligated with impunity, but the prospect of injuring the vena cava is not one to be faced with equanimity. The left-sided operation presents another grave possibility, for the affected glands are surrounding the origin of the inferior mesenteric artery. Hinman claims that the danger of tying this artery has been over-estimated, but I submit that in the human subject he has no grounds whatsoever for any such statement, particularly as in one case he did tie this artery and the patient died. For these reasons I am convinced that it is impracticable to remove completely the primary lymphatic field. Jamieson and Dobson expressed the same opinion in 1910, and in the last edition (1921) of Sir John Bland-Sutton's "Tumours, Innocent and Malignant" occurs this sentence: "My experiences of the operation leads me to agree with Jamieson and Dobson that the complete removal of the lymphatic area around the mesenteric and renal vessels is impracticable."

2. *Present Position of the Surgery of the Carcinomatous Lymphatic Glands.*—If the results of operative methods for carcinoma in general showed brilliant success and a high percentage of cures, it would be our bounden duty to elaborate some method which would overcome the difficulties enumerated above. But it cannot be gainsaid that there is widespread dissatisfaction with the results of operations for malignant disease. It is recognised that early cases do well, largely because no lymphatic involvement has occurred, but I think there are but few surgeons who will not give a bad prognosis when lymphatic dissemination is known to have taken place. I suggest that, amongst those who are earnestly considering this grave subject, many are coming to believe that once carcinomatous involvement of the glands is present, surgical procedures, however extensive, hold out but a faint hope of eradicating the disease completely. The trend of surgical opinion is reflected in the concluding paragraph of Clayton-Greene's[3] article on carcinoma of the tongue in Choyce's "System of Surgery." The modern operation for carcinoma of the tongue cannot be described as

a radical operation. Again, Lockhart-Mummery's brilliant perineal operation for carcinoma of the rectum cannot claim radical status. And lastly, we have the revolutionary doctrine of Douglas Quick,[4] who maintains that the outlook is made definitely worse by an attack on the lymphatics, because this leads to implantation of the growth of the cellular tissues, a more rapidly fatal condition. I am of opinion that an investigation along these lines is now urgently required.

3. *Analysis of Results.*—My contentions must necessarily fall to the ground unless I can bring forward results as good as those following the extensive operation. The best paper on this subject is by Hinman and others working with him. I shall therefore contrast his results and my own.

Hinman reports 79 cases with the following results:

Operative mortality	10 = 12·6 %
Deaths from metastasis	24
Alive with metastasis	6
Alive and well	34 = 43·0 %
Lost or incomplete data	5

These can be criticised under several headings.

Group 1A consists of 9 cases in which glands were palpable clinically before operation.

Group 1B consists of 13 cases in which the glands were so extensive as to be inoperable.

Group 2A consists of 25 cases in which no metastases were found in the glands removed.

Group 2B consists of 26 cases in which metastases were found.

Group 3. Six cases with incomplete data.

In Group 1A eight patients are dead and one alive with metastasis. This seems sufficient to lay down the principle that all cases with palpable glands before operation are definitely inoperable. It seems reasonable to suggest that the 22 cases of Group 1 were subjected to the radical operation quite unnecessarily with an operative mortality of 22·7 per cent. In Group 2A no metastases were found in the glands, and again the necessity for the radical operation is at least doubtful. There remains the group of 26 cases with metastases in the glands—the crux of the whole argument, for these must have all died eventually from a local orchidectomy. Hinman lays great stress on the fact that of these patients four are alive after four years and he claims in them a cure. Against that has to be placed a 12·6 per cent. operative mortality, which is a very considerable one.

I have been able to collect 23 cases from the records of the past 14 years at St. Mary's Hospital. Every effort has been made to trace these patients, and all of those alive and well except one of the most recent ones has been seen personally and thoroughly examined. My results in detail are:—

A. Cases treated by radical operation	1
Dead	1
B. Simple orchidectomy	22
Untraced	4
Dead	5
Alive with metasta	2
Alive and well	11 = 50 %

Analysis of five deaths from simple orchidectomy:—

Palpable metastases at time of operation	1
,, ,, + scrotal involvement	1
No palpable metastasis	1
Lived for 7½ years (cause of death unknown)..	1
Lived for 4½ years and died of pulmonary and laryngeal tuberculosis	1

Analysis of two alive with metastases. Both had palpable metastases, and a purely palliative operation was performed in each case to avoid threatened fungation through the skin of the scrotum.

Analysis of 11 alive and well:—

After 10¼ years	1	After 3½ years	1
,, 8½ ,, ...	1	,, 18 months	3
,, 4½ ,, ...	1	Less than 12 months ..	2
,, 4 ,, ...	2		

Results contrasted:—

	Hinman and others.	Author.	
Number	79	.. 22	
Operative mortality	10 (12·6 %)	.. Nil.	
Cases alive and well	34 (43·04 %)	.. 11 (50 %)	59 %
Cases alive for over four years, but dead from other causes	—	.. 2* (9 %)	

Of the two cases marked with an asterisk, one died 7½ years after operation from causes unknown, and one died 4½ years from tuberculosis of the lungs and larynx. As Hinman claims four years as the criterion for cure I may safely claim 13 cases. The points needing emphasis are that the radical operation has a serious operative mortality, whereas the simple orchidectomy has none. Moreover, the results of a local operation seem in no way inferior, but rather better; indeed, a recovery-rate of over 50 per cent. in malignant disease compares very favourably with the results of most carcinoma.

Auxiliary Measures.

In those cases which have palpable metastases, certain auxiliary methods of treatment must be considered in order that the patient may be given every possible chance.

(*a*) *X Rays.*—Deep radiotherapy has advanced considerably in the last few years, and it is now considered that localised growths can be attacked with some hope of success. Unfortunately, secondary growths from the testicle cover a wide area and lie very deeply. There is necessarily a limit to the X ray dosage which cannot safely be passed. The full skin erythema dose is so reduced when it arrives at the juxta-aortic glands that its therapeutic effect is small. Attempts may be made to "cross-fire" the growth from many angles, so reducing the danger of skin injury, but when this is done the cumulative dose reaches such a high degree that damage to the intestine cannot be prevented if a full therapeutic dose is to reach the glands. It is therefore not feasible to do much with X rays, an opinion confirmed by Orbaan.[5]

(*b*) *Radium.*—Precisely the same remarks apply to the results of radium therapy when applied over the skin. But radium implantation holds out slightly brighter prospects. A case reported by Taylor is interesting in this respect. A doctor had a malignant retained abdominal testicle with secondaries in the left iliac fossa, with compression of the vessels and œdema of the leg. Radium implantation gave great relief and enabled him once again to lead an active life. But 18 months later there were recurrences in the neck and elsewhere. Barringer and Dean claim moderate results, but Dr. Hayward Pinch tells me that he would hardly expect any really good results from radiotherapy in such deeply-placed metastases.

In conclusion, I have to thank my colleagues on the staff of St. Mary's Hospital for allowing me to use the material found in the clinical records. I have presented my results in a series of cases of simple orchidectomy, and have brought forward grounds to show that it is not a practicable, and therefore not a justifiable, procedure to attempt to remove the lymphatic field. A simple orchidectomy will cure a large percentage of cases if these are seen early enough. The population need educating to the fact that any enlargement of the testicle demands an immediate investigation as to its nature. The quotation at the beginning of this article emphasises a fact which is almost universally overlooked. While carcinoma and all other forms of malignant disease remain local, a purely local removal is alone required for success, but once the disease has begun to spread surgical procedures, no matter how extensive, show a very poor percentage of successful cures.

AUTO-HÆMAGGLUTINATION IN A CASE OF PERNICIOUS ANÆMIA,

WITH SUBACUTE COMBINED SCLEROSIS.

BY HENRY COHEN, M.D. LIVERP.,
EIT MEMORIAL RESEARCH FELLOW; HON. ASSISTANT PHYSICIAN, ROYAL INFIRMARY, LIVERPOOL;

AND

A. ROBY JONES, M.B. LIVERP.,
THELWALL THOMAS FELLOW IN SURGICAL PATHOLOGY, UNIVERSITY OF LIVERPOOL.

(*From the Thompson Yates Laboratories, University of Liverpool.*)

THE agglutination of a person's red blood corpuscles y his own plasma or serum—i.e., auto-agglutination –would appear from the literature to be of rare ccurrence in man. The case we record below was nder the care of Dr. John Owen at the Liverpool loyal Infirmary, and we are greatly indebted to him or permission to investigate and record it.

Brief History and Description of Case.

S. G., male, aged 52 years, married, had one child who ed at 9 years of age from "wasting." His wife is healthy id has had no miscarriages. Family history negative. o previous serious illnesses. For 15 months he has had iræsthesiæ of whole body, but especially of legs and et, and gradually increasing weakness of legs and loss of iergy.

On examination the typical features of pernicious anæmia ssociated with subacute combined sclerosis were present: mon-yellow tint, marked pallor, little wasting, typical glossitic" tongue, marked weakness with loss of joint, uscle, and vibration sense in upper and lower limbs, creased deep reflexes and bilateral extensor toe response, c.

The blood findings on admission were: Red corpuscles, 400,000 per c.mm.; hæmoglobin, 44 per cent.; white rpuscles, 8000 per c.mm.; differential count (per cent.) 1 400 white cells: polymorphs, 45·5; large lymphocytes, ; small lymphocytes, 45·75; mononuclears, 1·25; eosino- ils, 1·25; basophils, 0·5; myelocytes, 0·75. During this unt three normoblasts and four megaloblasts were seen. n Arneth count (per cent.) of the polymorphs gave: ass (1), 9·3; (2), 21·4; (3), 40·1; (4), 20·9; (5), 8·3; rneth index, 50·75. Blood film: Marked anisocytosis ith megalocytic predominance, poikilocytosis and poly- iromatophilia. No punctate basophils seen. Normoblasts id megaloblasts present.

Wassermannn reaction: Strongly positive. Fragility red cells and coagulation time of blood (method of Dale id Laidlaw): Normal. Van den Bergh reaction: Negative rect; positive indirect reaction. Urine: Excess of urobilin d urobilinogen. Fæces: No parasites; no occult blood. actional gastric analysis: Complete achlorhydria with very low total acidity (10 c.cm. N/10 HCl per cent.); blood nor bile.

Auto-agglutination was noticed during the routine blood amination. In diluting the blood for a cell count and in e preparation of blood films the phenomenon declared elf. That it was due neither to the apparatus nor to the lutions used was apparent from its repeated occurrence th new apparatus and fresh solutions. Moreover, on the me glass slide on which the auto-agglutination occurred th S. G.'s blood, blood from other patients remained n-agglutinated.

In order to study further this phenomenon of ito-agglutination, blood was withdrawn by venous incture. A portion of this was allowed to clot and e serum collected; the remainder was citrated to event clotting, immediately centrifugalised, and e red cells carefully washed with warm saline 7° C.).

Results.

The following tables show the effects of varying lutions of S. G.'s serum on his own cells and those other groups at body and room temperature. ie cells and serum of pure members only of the four ood groups were used in this investigation.

The red cells of S. G. were not agglutinated by the serum any normal blood group either at body or room nperature.

Tables showing effect of S. G.'s serum (diluted with normal saline) on the cells ($2\frac{1}{2}$ per cent. suspension in normal saline) of the blood groups I., II., III., and IV., (A) at 37° C. and (B) at 12° C. (room temperature).

	A.					B.				
Cells of group—	Dilution of S. G.'s serum.					Dilution of S.G.'s serum.				
	1/2	1/6	1/18	1/54	1/162	1/2	1/6	1/18	1/54	1/162
I. ..	+ + +	+ +	+ +	+	+	+ + +	+ + +	+ + +	+ +	+ +
II. ..	+ +	+ +	+	+	+	+ + +	+ + +	+ +	+	+
III. ..	+ +	+ +	+	+	–	+ + +	+ +	+ +	+	–
IV. ..	–	–	–	–	–	+ + +	+ + +	+ + +	+ +	+
S. G. ..	–		–	–	–	+ +	+		–	–

+ + +, complete agglutination; + +, marked but not complete agglutination; +, slight but definite agglutination; –, no agglutination.

Certain facts which emerge from a study of the above are:—

1. The patient belongs to blood group IV., and his serum contains the iso-agglutinins for groups I., II., and III.
2. The power of auto-agglutination does not reside in the red corpuscles, since S. G.'s cells are not agglutinated by the serum of a normal member of any blood group.
3. Auto-agglutination occurs only at low temperature. If tubes containing S. G.'s blood be gradually cooled auto-agglutination begins to appear at 22°–26° C.; if, after cooling, the same set of tubes be gradually warmed, auto-agglutination remains in some degree until 32°–34° C. is reached, thus demonstrating the reversibility of the reaction.
4. (*a*) The agglutinating power of S. G.'s serum is for all groups greater in the cold than at body temperature. (*b*) The agglutinating power in the cold of S. G.'s serum is greater for cells from normal members of his own group (IV.) than for his own cells.

Additional facts we have determined are:—

5. The auto-agglutinin of S. G.'s serum agglutinates the cells of—
   (*a*) Rabbit (dilution of serum 1/486 +).
   (*b*) Guinea-pig (dilution of serum 1/162 +).
   (*c*) Sheep (dilution of serum 1/18 +).
   (*d*) Goat (dilution of serum 1/18 +).

Other workers have shown, and our observations confirm, that this agglutination is distinct from that due to hetero-agglutinins normally present in serum.

6. Auto-agglutination is associated with the removal from the serum, by the red cells, of the auto-agglutinin*; for if S. G.'s serum be mixed with a suspension of his cells in the cold, allowed to stand and the mixture be then centrifugalised, the supernatant fluid does not contain the auto-agglutinin, though the iso-agglutinins for groups I., II., and III., can be demonstrated.
7. There is no evidence of auto-phagocytosis in S. G.'s blood (Prof. E. E. Glynn); nor of any auto-hæmolysis.

Discussion.

Clough and Richter,[1] in their paper A Study of an Auto-agglutinin occurring in a Human Serum, have recorded fully a case of chronic mitral endocarditis with broncho-pneumonia which showed this phenomenon. They make no reference, however, to its occurrence in trypanosomiasis, clinical and experimental, probably the commonest condition by far with which auto-agglutination is associated, and they appear to have overlooked a paper by Warrington Yorke,[2] in which are recorded fully and accurately the effect of temperature on auto-agglutination, the adsorption of agglutinin by the red cells, the reversibility of the process, and the effect of the agglutinin on the cells of other animals.

Clinically, auto-agglutination has been observed in the following conditions:—

1. Trypanosomiasis (Kanthack, Durham, and Blandford [3]; Christy [4]; Dutton and Todd [5]; Martin, Leboeuf, and Roubaud [6]; Yorke,[2] &c.).
2. Cirrhosis of the liver (Reitmann [7]; Klein [8]).

---

[*] Adsorption of agglutinin by the cells: this is supported by the reversibility of the process—i.e., on warming, the auto-agglutinin is liberated.

3. Relapsing fever (Todd [9]; experimentally in rats by Nattan-Larrier [10]).
4. Syphilis (Dudgeon [11]; Todd [9]).
5. Long-standing epilepsy (Dudgeon [11]).
6. Certain forms of icterus due to hæmolysis (Martin and Darré [12]).
7. Broncho-pneumonia with chronic mitral endocarditis (Clough and Richter [1]).
8. Marked secondary anæmia due to hæmorrhage from hæmorrhoids; and heart disease (Kliger [13]).
9. Pernicious anæmia with subacute combined sclerosis and a positive Wassermann reaction (Cohen and Jones).

Apart from trypanosomiasis, in which auto-agglutination is said to occur in the large majority of cases, the literature contains references to only one or two cases of the above conditions in which auto-agglutination was found, and some of these are doubtful. One of us (H. C.) has examined the bloods from 300 individuals since the occurrence of our case, but not one showed the marked auto-agglutination found in S. G. Those examined included 11 cases of pernicious anæmia—6 with subacute combined sclerosis, 4 cases of cirrhosis and syphilis of the liver, 3 cases of hæmolytic icterus, and many severe secondary anæmias. Forty of these cases were associated with a positive Wassermann reaction. We must conclude that auto-agglutination is thus a rare phenomenon, not constantly associated with any pathological state.

The daughter of Clough and Richter's patient [1] showed auto-agglutination in her blood. They suggested that since it was present in both mother and daughter, the phenomenon is an hereditary peculiarity. The only living relations of our patient, an elder brother and his son, showed no auto-agglutination, both of them being normal members of group IV. That auto-agglutination can be acquired is shown not only by its very frequent occurrence in trypanosomiasis, but also by the experimental work of Rous and Robertson,[14] who were able to induce auto-agglutination in rabbits by the repeated withdrawal of moderate quantities of blood.

In view of this experimental work we examined the blood of the following five donors:—

1. R. H. P., who between June, 1921, and August, 1924, had on each of six occasions given one pint of blood.
2. T. H., who between February, 1922, and July, 1923, had on seven occasions given one pint of blood.
3. W. L., who had in January, 1921, also in May and June, 1924, given one pint of blood.
4. W. H., who had in March, 1923, given one pint of blood.
5. W. H. E., who during the past three years had almost weekly given 20–50 c.cm. of blood for experimental purposes, and in July gave one pint of blood as a donor.

All these cases proved negative, no trace of auto-agglutination being found.

Of the mechanism of production and the chemistry of the auto-agglutinin we are ignorant. Its occurrence in anæmias has led to the suggestion that the auto-agglutinin results from the inoculation of the organism with the products of disintegration of its own erythrocytes, but this seems negatived not only by the very rare occurrence of auto-agglutination in anæmic states, but also by the impossibility of experimentally producing an auto-agglutinin in the blood of an animal by injection of its own red cells.

Another suggestion, that the auto-agglutinin develops in direct response to the stimulus of a pathogenic agent, is of interest in view of the similar protozoal ætiology of trypanosomiasis, relapsing fever, and syphilis, conditions in which auto-agglutination has been clinically described. The increased acidity of the blood said by Nierenstein [15] to occur in trypanosomiasis has been suggested by Breinl and himself to be the cause of auto-agglutination in that disease.

Can auto-agglutination be looked on as part of the body's resistance to disease? Since the phenomenon does not occur at body temperature, any effect it will exert is probably at the surface. Its only value here would seem the diminution of bleeding from small wounds by plugging the vessels with agglutinated cells, and thus preventing the further impoverishment of the blood volume in severe anæmias.

Practically recognition of the phenomenon of auto-agglutination may account for some of those cases, which, when grouped by the glass-slide method with the sera of groups II. and III., are said to show a change in group from IV. to I., when typed at a later date. Thus, had S. G. been tested by this method, he would have been called group I., because his own serum would agglutinate his erythrocytes even when mixed with serum of group II. or III. The consequences of transfusing a patient with blood from a donor who shows auto-agglutination is not likely to have serious effects, provided the blood be slowly injected, since the body temperature prevents the occurrence of the auto-agglutination.

Whilst, therefore, the practical advantages which result from a study of auto-agglutination in human blood seem small, its scientific interest is considerable.

Note.—Since the above paper was written a further case of auto-agglutination in pneumonia is recorded by E. Claveaux and Pérez Sánchez.[16] The phenomenon was noticed during convalescence from the disease. The acute attack had been treated with injections of patient's own blood.

Clinical and Laboratory Notes.

A CASE OF
DUODENAL ULCER IN AN INFANT.

BY AMY M. THOMS, M.D. ST. AND., M.R.C.P. LOND
LATE HOUSE PHYSICIAN, QUEEN'S HOSPITAL FOR CHILDREN, LONDON.

DUODENAL ulcer is regarded as a rare condition i infants, the diagnosis of which is difficult and seldo made during life. Dr. Donald Paterson,[1] in a revie of the literature, states that of 100 reported cas there were only three in the United Kingdom, an to these he adds two of his own. The following cas therefore, which occurred at the Queen's Hospital f Children, seems worthy of record.

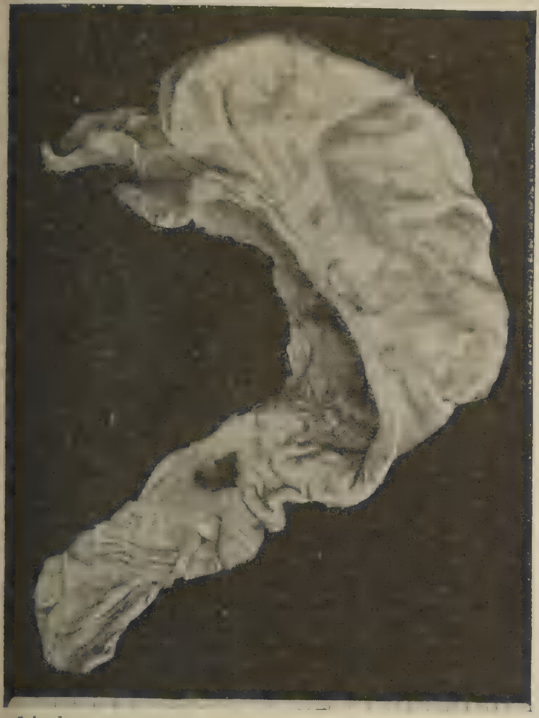
R. C., a male infant aged 5 months, was admitted o Nov. 1st, 1922. He was the first child of young healt parents, and there had been no previous miscarriages. I was a full-time child and had been bottle-fed on vario foods, but never throve except during his third and fourt months. Before coming to hospital he had been attendi a welfare clinic, where his feeds were carefully regulate There had always been a tendency to vomiting, and h feeds had been reduced in amount to 1 oz. every two hou and he usually vomited a little of each. He had scream after food until a few days before admission. Flatulen and constipation were very troublesome.

Condition on Admission.—He was a small wasted chil weighing 7 lb. 13 oz., with no obvious organic disease. I continued to be constipated and vomited slightly at tim generally after feeds, and had lost 5 oz. in weight by Nov. 6t n the evening of the 8th he vomited bright blood-stained uid and was collapsed. A stool seen at this time had some nelæna-like staining. The next day he seemed well till vening, when he suddenly collapsed and died.

---

[1] THE LANCET, 1922, i., 63.

Post-mortem Examination.—A punched-out ulcer was ound in the first part of the duodenum, situated on the osterior wall about ¼ inch from the pyloric sphincter. It



as about three-eighths of an inch in diameter, irregular in iape, with slightly undermined edges. The floor consisted submucous tissue on which could be seen a small vessel om which the bleeding had occurred. There was no ickening and very little evidence of inflammatory reaction the surrounding structures and no peritonitis. Altered ood was present in the lower part of the ileum, and there as slight injection of the Peyer's patches, but otherwise othing abnormal was found.

I am indebted to Dr. C. Alice King for permission to ublish the case and the accompanying photograph.

A CASE OF NTESTINAL OBSTRUCTION COMPLICATING PREGNANCY.

BY JOHN C. JEFFERSON, F.R.C.S. ENG.,
HON. SURGEON, ROCHDALE INFIRMARY.

THE following case seems to be of sufficient interest justify its being recorded.

Mrs. L., aged 27, was operated upon in 1916 for acute osalpinx with pelvic abscess on the right side. The right be and ovary were removed and the abdomen drained. e made a good recovery, and three years later gave birth a child without any complication.

I was asked to see her on Feb. 12th last, her doctor having agnosed acute intestinal obstruction. She was now again egnant, about seven months. Until 36 hours before I saw r she had been in good health. The present illness had mmenced with acute pain in the right iliac fossa; she had mited immediately, and vomiting had been incessant ever ice. The bowels had not been opened since the beginning the illness despite aperients and enemata. The temperature as 98° F., pulse 120.

On examination the abdomen presented a linear scar of the evious right rectus incision. The uterus, which reached the vel of the umbilicus, was pushed well over to the left side a rounded tympanitic swelling occupying the right iliac ssa. The upper abdomen was also distended, and peristaltic ovements were observed.

Operation.—She was at once removed to hospital, where I opened the abdomen through an incision parallel to and a little outside the previous one. It was then found that the tympanitic swelling referred to above was caused by a coil of distended small intestine which was strangulated between a stout peritoneal band and the uterus, the band passing from the right broad ligament to be attached to the uterus at the site previously occupied by the utero-tubal junction. On relieving the strangulation I found the coil to consist of the last 18 inches of the ileum, the ileo-cæcal valve having escaped inclusion by half an inch. The gut was in such poor condition, and I doubted its viability so much, that I judged it safest to resect. This was done, the ileo-cæcal valve, which was somewhat œdematous and ecchymosed, closed, and an end-to-side anastomosis of ileum and cæcum performed.

The patient made a good recovery and the pregnancy continued to full term.

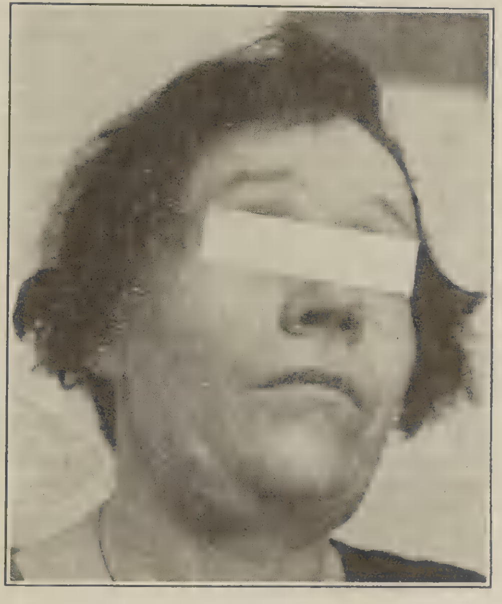
The peritoneal band was almost certainly a product of the old pelvic inflammatory trouble of six years ago. It appears most likely that while the uterus remained normal in size the band was lax, but with the rise of its uterine attachment during pregnancy it became taut and so an agent of strangulation. It is somewhat remarkable that it caused no trouble during the previous pregnancy.

A BILATERAL TUBERCULOUS INFECTION OF THE SUBMAXILLARY SALIVARY GLANDS.

BY H. J. SIMSON, M.B. EDIN., D.P.H.,
LATE TUBERCULOSIS MEDICAL OFFICER, SOUTHAMPTON;
AND
A. MASSEY, M.B., D.P.H. LEEDS,
ASST. M.O.H., SURREY C.C.

THIS condition is, perhaps, of sufficient rarity to warrant the description of a seemingly typical case, seen recently at the Southampton Municipal Dispensary.

The patient, a woman, aged 32 years, suffered from pneumonia in September, 1922. First seen at the Municipal Dispensary on Dec. 27th, 1922, when the following symptoms were elicited—viz., cough, expectoration, shortness of breath, lassitude, poor appetite, and vague pains in chest. Physical examination on that date revealed extensive tuberculous disease throughout the left lung, with cavitation at its apex. The upper lobe of the right lung was also involved. There was no enlargement of glands of neck; hypertonicity of the sternomastoids was noted, and the tonsils appeared normal. In the sputum were many tubercle bacilli. Weight was 6 st. 3¾ lb.



Bilateral tuberculous infection of submaxillary salivary glands.

Patient was admitted to Borough Sanatorium on Jan. 4th, 1923, and discharged therefrom on June 11th following. During the whole of this period pyrexia was a notable feature; no improvement was effected in the lung condition, and weight was 5 st. 12 lb. on discharge. Since then the lung condition has become progressively worse, and repeated sputum examinations have all proved positive. Some six weeks prior to discharge from sanatorium the patient first complained of a small swelling on each side of the under surface of the lower jaw. The swellings slowly enlarged, until they assumed the conspicuous proportions shown in the photograph, taken on March 24th, 1924. The swellings are symmetrical, hard, and somewhat irregular on palpation, and tender to firm pressure. They are essentially chronic in character. There is no enlargement of lacrymal or parotid glands; the teeth are perfectly sound, the throat and tongue present a normal appearance, and the Wassermann reaction is negative.

A diagnosis was made of tuberculous infection of submaxillary salivary glands.

Medical Societies.

HUNTERIAN SOCIETY.

A MEETING of this Society was held on Oct. 20th, when Mr. H. W. CARSON gave his Presidential address, entitled

THE WATERSHED OF MEDICAL PRACTICE.

He took as his theme the factors influencing the decision as to whether, in the treatment of any patient, operative or non-operative measures should be adopted—factors as slight sometimes as the pebble's edge or slanting stone which may decide the course of a stream The decision as to which path to choose had become more and more difficult as the science of medicine and surgery had developed. It was not long ago when at our hospitals medical and surgical cases were so well differentiated that they could be, and were, sorted out without difficulty by the porter in the casualty department. Nowadays this work had to be done by a skilled physician trained to make rapid diagnosis, and even then references to other departments are common. The scope of abdominal surgery had been immensely increased, and it was here chiefly that one saw the conflict between the operators and the non-operators. Not without a struggle did the physicians relinquish the acute abdominal patient. Mr. Carson said that in his own student days these cases were all admitted under the physicians, who might or might not invoke the aid of their surgical colleagues. It led, of course, to delay and loss of life, and gradually, as operation began to be accepted as the only treatment for these abdominal emergencies, the surgeon was summoned more and more quickly, and eventually, with a great wrench, the acute abdominal case was admitted under the surgeon. In the treatment of the myriad surgical diseases which give rise to indigestion, again, the surgeon had thrust forward a formidable salient. The advance had not been without its serious failures and withdrawals. The attack started with the discovery that the appendix might be responsible not only for the gravest forms of peritonitis, but that in its more or less quiescent stages it could account for much ill-health, not only in the abdomen, but elsewhere. Then followed a discreditable period when appendicectomy was exploited to such an extent that even the lay press ridiculed it.

Diseases of the Intestinal Tract.

The next important move was into the treatment of diseases of the stomach, where the advent of the surgeon did much to sweep away the fog which had settled around the word "indigestion." He came at the right moment, at the time when the biochemist and the radiologist were racing to his help. It was indeed a happy conjunction. But here again the operation of gastro-jejunostomy was hailed as a panacea, and even to-day the memory of the unfortunate results which followed the performance of this operation in unsuitable cases led occasionally to a refusal to adopt it in some cases where it would be the ideal treatment. A little later all ills were ascribed to defects in our "cesspool" system of intestinal drainage and our teeth were all condemned, with the result that short-circuiting and colectomy were done indiscriminately and teeth were extracted by the million. But even apart from these extreme cases there were conditions about which there was an honest difference of opinion. For example, a patient was sent to Mr. Carson by a medical man, with a diagnosis of gall-stones. With this diagnosis he agreed, and an X ray picture showed the stones quite clearly. He advised operation, but the patient wished first to consult a distinguished physician. The physician agreed with the diagnosis, but deprecated an operation, since in his opinion the attacks, if they recurred, would yield to simple treatment; in short, he advised the patient to put up with the slight inconvenience which these attacks might entail. Here there was a curious variation of opinion. Surgeons were convinced that a residual gall-stone was a perpetual menace; serious complications might occur at any moment, and experimental evidence proved gall-stones to be an exciting cause of cancer of the gall-bladder. One could only believe that the physician for some reason had come to the conclusion that the risk of operation was so great in this case that it was better to chance the complications and put up with the disability. The treatment of duodenal ulcer was another problem in the solution of which surgeons and physicians differed. In the case of chronic gastric ulcer there was less divergence of opinion, and in Mr. Carson's opinion operative treatment was steadily gaining ground. He thought this could be explained by the serious disability incurred, the rarity of quiescent periods of good health, the very serious and crippling complications, and the very real menace of cancerous degeneration. But in one complication of chronic gastric ulcer surgeons themselves disagreed as to the wisdom of operation, that is, in the treatment of severe hæmorrhage. At the present time there was a majority against operating for the control of hæmorrhage. There was plenty of evidence that such an operation might have to be very extensive—for the much-extolled gastro-jejunostomy was valueless in such cases—and had a heavy mortality, while, on the other hand, the actual mortality from hæmorrhage was known to be small. It seemed the better practice to tide these patients over the hæmorrhage and to do the curative operation later.

Exophthalmic Goitre.

Another disorder in which surgery held out an increasing chance of cure was exophthalmic goitre, and here was perhaps the ideal association of physician and surgeon. It had long been recognised that exophthalmic goitre was very resistant to medical treatment, and when the subject was thrashed out at the Royal Society of Medicine in 1912, a mortality under medical treatment of 25 per cent. was accepted; at most 10 per cent. were cured, and that only after years of invalidism. The surgeons estimated the mortality of cases treated by operation at 5 per cent. or less, and the prospect of cure at between 70 per cent and 80 per cent. Since then more work had been done and it was beginning to be recognised that there was a prospect of cure by medical means if treatment could begin in the first six months of the illness. Therefore, surgery was not employed during this period, nor was it considered wise to operate during an exacerbation. Here there was no antagonism between operators and non-operators, but a realisation that a disease might require different treatment at different stages of its progress. There were, however, certain difference of opinion, not in surgical versus medical treatment, but in non-operative versus operative treatment of a purely surgical disease. Not very long ago every surgical ward had n it patients who had been operated upon for tuberculous disease of the bones or joints. Where were hose cases now ? They had learnt by bitter experience that operation was not the way to treat any but a quite small minority of these cases, and, with the ncrease of institutions where time could be given o conservative methods, such as the Treloar Hospital at Alton, a new hope was arising for these unfortunate victims of surgical tuberculosis. Many were being restored to health with useful limbs who formerly would have been condemned to mutilation or even death.

Physicians and Surgeons.

Reverting to his text, Mr. Carson proceeded to onsider what pebble's edge influenced one doctor o become a physician and another to become a urgeon. The distinction between the two branches of our science was becoming less pronounced. It was now accepted that the problems of the surgeon were no less complex than those of his medical olleague, and that the surgeon was not merely the raftsman who exercised his art at the bidding of the uperior branch of medical learning. It was to be hoped that the apparent antagonism between phyician and surgeon might merge into a real collaboraion of medical and surgical science, since the same isorder might require at its different stages the most iverse treatments.

SOCIETY FOR THE STUDY OF INEBRIETY.

COCAINE ADDICTION.

THIS Society held a meeting at the house of the Medical Society of London on Oct. 14th. Sir WILLIAM WILLCOX, the President, was in the chair.

Prof. W. E. DIXON read a paper upon Cocaine Addiction. He first referred to the immemorial ractice among the Indians of the West of South America of taking coca leaves as a stimulant in mental nd physical fatigue, a practice which survived to his day amongst the natives of Peru. General Miller sed coca leaves for his army in his campaign of 1824 nd was much impressed by their value, whilst Montegazza, in 1859, stated that he obtained great muscular and mental energy from a small dose of an nfusion of the leaves and " unthinkable beatitude " from a larger one. No such pleasant effects had ollowed an injection of 1½ gr. of cocaine in the ase of the speaker, but, on the contrary, he suffered rontal headache, excitement, increased reflexes, and nsomnia. Others had recorded similar experiences with cocaine, but it was possible that the alkaloid did ot reproduce the whole effect of the fresh coca leaves.

ction of Stimulants upon the Central Nervous System.

Cocaine had an action on the central nervous ystem which corresponded with a stimulation of the hole cerebral cortex, so that after injection into nimals convulsions could be produced by electrical imulation of the cortex, which were abolished by vering the crura cerebri. The dose per unit of bodyeight necessary to produce convulsions in animals as proportioned to the degree of development of the rebral hemispheres. In man the exaltation of eling and increased muscular and mental vigour were ue to the stimulation of the cerebral cortex. Other rugs were known which produced similar effects ; bsinthe, picrotoxin (a fish poison), camphor, atropine, nd nutmeg were examples. Devotees of absinthe ecame restless, excitable, tremulous, and ataxic, nd sometimes suffered from delusions and epileptiorm convulsions with, later, permanent derangement intellect, just as occurred with cocaine. Atropine, though having similar effects, did not, as a rule, give se to a " habit " on account of its unpleasant sidefects, while the action of caffeine was much more ild and prolonged and was chiefly confined to the gher intellectual centres, the motor areas being rely influenced.

Acute Cocaine Poisoning.

As a rule, ½ gr. of cocaine produced little effect and 1½ gr. was well tolerated by ordinary persons. The fatal dose varied from 8 to 23 gr., but as with other drugs which acted upon the central nervous system the effect of cocaine in different individuals was uncertain. Death was due to shock from sudden paralysis of the central nervous system, for while the effect of a small dose was to stimulate, over-stimulation by a large dose produced the reverse effect—namely, paralysis. This was an everyday maxim which was not sufficiently appreciated in the case of collapse and death from the absorption of cocaine in a susceptible person. In every case of death from the use of cocaine or similar substances as local anæsthetics, the symptoms were strikingly like those produced experimentally in animals. Prof. Dixon added two comments: first, that death was always due to sudden absorption ; when steps were taken to render absorption slow, as by the use of a tourniquet, the alkaloid was apparently adsorbed locally to a great extent. This was the reason for the addition of adrenalin to cocaine solutions for local anæsthesia ; the principle was a good one, though adrenalin actually added to the toxicity of the solution when it was absorbed rapidly. The second comment was that cocaine was much more dangerous in strong than in weak solutions, for the latter favoured innocuous adsorption into the tissue colloids. It was well recognised that tolerance to cocaine could be rapidly established by practice in man, so that a dose of 20 gr. could be taken without ill-effect after a month. This effect was confined to man ; in laboratory animals such tolerance could not be established.

Effect of War Conditions on the Cocaine "Addict."

Before the war cocaine was rarely used by the " addict " except in conjunction with morphia. Generally the morphine habit was contracted first ; more rarely the addict first became enslaved to cocaine. The reason for this was that the symptoms of one drug habit were relieved by the other ; some physicians even prescribed cocaine as a means of escape from the morphia habit. In many cases the cocaine habit was contracted from the legitimate use of the drug as a nasal spray in hay fever or asthma. The habit was never common in this country, but was more prevalent in America, France, and even India ; in the first country it was a social problem even before the war, and was rapidly increasing in the numbers of its victims. It had been stated that an alarming increase had followed the introduction of prohibition in America, but Prof. Dixon pointed out that the increase had been a steady one over many years, and though doubtless affected by post-war conditions, could not be fairly attributed to the sudden withdrawal of alcohol. In India cocaine taking was confined to opium or ganja addicts, by whom cocaine powder was taken mixed with betel leaves and slaked lime.

A change occurred in the early days of the war. Cocaine users, who took the drug as a rapid intoxicant, became common in Paris where the alkaloid could be readily obtained from habitués of cafés and music halls. The drug was taken either by sniffing the powder or mixed with an alcoholic beverage. Many of the persons who took cocaine were not true addicts, but resorted to the drug only rarely and upon special occasions at " cocaine debauches," running the risk of acquiring the habit without actually doing so. None the less, such persons were a danger to themselves and others, and constituted a serious problem in State medicine. In the speaker's opinion they should be isolated like cases of infectious disease, thus removing a source of infection of others with the cocaine habit.

Once formed the cocaine habit was perhaps the worst of all drug habits, for it led to more rapid mental, moral, and physical degradation than the depressant drugs such as morphine. The morphinist retained some desire for freedom, but the cocainist cared for nothing, his mind was completely bemused.

Cocaine induced insomnia. loss of appetite, dyspepsia, and diarrhœa, and sometimes delusions and deafness. A delusion of feeling a foreign body—sand or worms—under the skin was diagnostic of cocaine. In spite of all this the habit was comparatively easily cured, for even when 10 to 30 gr. a day had been taken, the drug could be completely cut off at once without any ill-effects, whereas a similar withdrawal in the case of the heroin habit would certainly jeopardise life.

Characteristics of Drug Addicts.

Drug addicts were not normal people who had availed themselves of opportunities for indulging in drugs—for normal persons did not derive pleasure from their first experience of cocaine. In 1906 Sir Clifford Allbutt and the speaker, in a joint article, defined the people who took an immediate pleasure from drugs as "neurotics." Quickness and sensibility, acute perception, and alert muscular reaction were qualities of high breeding, but they became morbid when developed in excess in the lower ranges of sensibility without check from the higher controlling centres. When Laséque said, "It isn't everybody who can become an alcoholic," he meant that there must be a pre-existing mental state. The same was even truer of drug takers than of alcoholics, and it was apparent to all who had much experience that drug taking was rather a symptom of a certain type of mental condition than a disease in itself. Proof of this lay in the fact that those who contracted the habit as a result of the use of a drug in disease were much more readily cured than other addicts. The Americans were now discussing whether drug taking was a medical issue or a police problem, since 98 per cent. of the "police cases" of drug addiction were associated with crime or a criminal environment. But the chief of the New York "Narcotic Police" pointed out that drug addicts made poor criminals, being lacking in judgment, self-control, and will power. To treat them all as criminals would, therefore, be as unfair and unsuccessful as was the mediæval treatment of lunatics. The cocaine habit was spreading over the world; it had appeared in France, Germany, Italy, Spain, and England, but was less common in Europe than in America and the East. The narcotic division of the New York police had arrested 8174 drug takers during 1923, of whom 95 per cent. used heroin, either alone or in conjunction with cocaine.

Treatment of the Drug Habit.

Drug addicts fell into two classes, a smaller class who contracted the habit from the legitimate use of a drug to cure pain in disease, and a larger in whom addiction was a sign of neurosis. The first step in treatment was to restore the patient to physical health. The problem of relieving the mental damage then arose, for if the patient were allowed to return to his old associations relapse was certain. Few addicts would come for treatment as long as a supply of the drug was available or until the drug had lost its effect. They might then allow themselves to be "cured" in order to renew the habit with fresh pleasure.

In conclusion, Prof. Dixon made the following propositions: (1) That prosecution of cocaine traffickers should be carried out by all means at our disposal; (2) some form of international control, to prevent illicit importation of cocaine or coca leaves, should be established; (3) as most of our cocaine is prepared in German laboratories, this supply should be controlled at the source; (4) that information should be spread of the gravity and danger of the use of narcotics not only to medical men and medical students, but also to members of the teaching profession.

Discussion.

Dr. H. H. Dale had been told that cocaine taking was a social habit and not, as in the case of morphine, a secret vice, for cocaine was taken not to combat insomnia, but to produce it. Hence cocaine taking was limited to big cities, where it was taken to stimulate the flagging appetite for pleasure.

Dr. A. J. Copeland discussed the action of a numbe
of cocaine substitutes, including butyn and novo
caine, and pointed out that in appropriate doses a
produced convulsions in animals exactly similar t
those produced by cocaine. From his own persona
experience of one of these drugs, he considered tha
they were just as likely to give rise to a "habit
as cocaine itself.

Dr. W. C. Adams was interested in the suggestio
that the effects of coca leaves and of cocaine migh
be different. It was possible that the inherite
psychology of different races might have somethin
to do with the different effects upon them of th
coca leaf.

Dr. Harry Campbell pointed out that a non
toxic substitute for cocaine would be most useful, an
read a letter from Dr. Francis Hare to the effect tha
the cocaine habit was in his (Dr. Hare's) experienc
comparatively rare in this country. Dr. Campbe
suggested that the "neurotic" temperament whic
Prof. Dixon had said was at the root of the cocain
habit might be due to a condition of the blood, an
pointed out that certain habits, such as alcoholism
often exhibited a degree of periodicity. Such
periodicity had been noticed in some cocaine takers.

Dr. O. Inchley felt that the outlook was not
very happy one if the habit was due to a neuroti
mental condition, since that was inborn and no
readily affected by any treatment.

The Rev. H. Goyen (Victoria, Australia) said tha
in Australia they had lessons in schools and college
on the dangers of alcohol and drug habits, but tha
more harm than good was sometimes done by ove
exaggeration of the dangers. He thought that th
real facts as to the causes of the increase in dru
taking in America should be made known, as muc
capital was being made of the increase by those wh
opposed prohibition. His impression was tha
cocaine addicts very rapidly became hopeless soci
derelicts.

Dr. Eleanor Lowry said that it had been suggeste
that in some cases of murders by members of th
Irish Republican Army the men entrusted with th
deed had been "doped" either with alcohol or drug
She believed that, on the contrary, only men wh
were known to be free from any such vice we
selected for such work.

The President remarked that no cases of murde
by cocaine had come under his notice, though suicid
by cocaine was not uncommon. In cases of acut
cocaine poisoning the stomach should be washe
out with a solution of potassium permanganat
The prognosis in the case of cocaine was fairly goo
if this treatment were instituted within an hour
the taking of the drug, since the alkaloid was relativel
unstable and easily broken down. The use of cocain
as a local anæsthetic was by no means free fro
danger—three fatal cases had occurred at his ow
hospital following the use of cocaine in the urethr
He was surprised that more accidents had n
occurred in nose and throat practice, where sol
tions as strong as 10 per cent. and even the pu
powder were occasionally used.

Prof. Dixon replied briefly.

LONDON DERMATOLOGICAL SOCIETY.

An ordinary meeting of this Society was held o
Oct. 15th at St. John's Hospital, with Dr. Knowsle
Sibley, the President, in the chair. Twenty Fello
and visitors were present. The report of the path
logical subcommittee on a case of erythroderm
previously shown, was read. The committee unan
mously considered the case to be one of lymphat
leukæmia. Pathological specimens were shown b
Dr. A. Knyvett Gordon, clinical cases by the Preside
and by Drs. W. Griffith and S. R. Kapoor. Th
cases and specimens were discussed by the Presiden
and Drs. Griffith, Kapoor, Howard Humphris, J. A.
Orlebar, R. F. Fagan, and Knyvett Gordon.

ROYAL SOCIETY OF MEDICINE.

SECTION OF DERMATOLOGY.

THE first sessional meeting of this section was held n Oct. 16th, under the presidency of Dr. E. G. RAHAM LITTLE.

Dr. PROSSER WHITE read a paper entitled

Bakers' Eczema: A Clinical and Experimental Inquiry.

e said that in France bakers' eczema was unknown, hile in regard to America a long bulletin issued by ie United States Government did not mention the ondition. It had been known for many years in this ountry that cases of eczema occurred from time to me among persons engaged in the making of bread id confectionery, and the object of the inquiry he t out to make was to ascertain whether this skin ondition was attributable to the flour used or to iy particular ingredient or "improver" incorporated ith it. This dermatitis seemed to trouble confeconers more than it did bakers. When 10 per cent. yeast was employed in bread-making, it was ispected that this might be an agent in causation; it it appeared that workers in dried yeast did not iow any particular incidence of eczema. Neither d water seem to be a cause, though in the experients the addition of water was needed to set up the rmatosis. Another question was as to whether the rocess of bleaching the flour was responsible for the ondition of the skin. Acid calcium phosphate was rgely used in the making of confectionery to replace ie old tartaric acid. Or was the eczema due to otein sensitisation? Dr. White suggested that it ould be interesting to inquire whether people in iese trades who claimed compensation had a imary morbid condition of the skin, so that the sh was merely incidental and not caused by their cupation.

The bleaching of the flour was carried out with tric oxide, sometimes with chlorine. The so-called nprovers and activators increased the hydrogen-ion oncentration in the dough. Millers introduced 1 oz. salox—an ammonium sulphate and ammonium perlphate preparation—into a 280 lb. sack of flour—., 1 part in 4000, and acid calcium phosphate, 1 part 290. The kneading of a full batch of bread occupied to 45 minutes, and the first stage, the dissolving of ie salt, was always done by hand. It appeared that for ie salt to act as a definite irritant it was necessary r it to be on the skin in the form of crystals. Two en and a woman subjected themselves to experiment this and other points, and it was found that an ythematous rash appeared only when the salt was tained on the arm in crystalline form. Into onfectionery, of course, sugar entered largely, but in ealthy persons engaged in this industry it did not ppear to be a cause of dermatitis. Observations were ade by Dr. White, by means of the three volunteers ready mentioned, concerning various kinds of flour, id flours which had been treated in divers ways. s a general result of three days' tests, irritation of the in could be declared to be uncommon. In some ses when the paste was wet there were eruptions, it they remained confined to the site of application, id treatment quickly healed them. Some irritation llowed the application to the skin of acid calcium iosphate, especially if incorporated in untreated branny" flour. It was rare for the baker or the onfectioner actually to handle dough for more than vo hours daily.

It would be interesting to learn, he said, whether kers and confectioners suffered from eczema oportionately more than did the general population. he figures he was able to glean showed they did not, id he was not in a position to say that there was any sh peculiar to the trades in question. Sufferers from zema should not be allowed to work at food industries hile they had the disease, especially as the workers these trades objected to the use of rubber gloves.

Discussion.

Dr. ALLAN PARSONS said that two years ago he was deputed by the Ministry of Health to investigate the conditions associated with an epidemic of "bakers' itch." The conclusion he arrived at was that a great number of the cases of this disease, so-called, could not truly be described as instances of dermatitis due to baking. Many of the cases he saw could be accounted for in other ways. Also, the majority of the supposed cases occurred among employees in shops which were not equipped with machinery, and whose hands and arms were therefore immersed in the dough for a good part of each day. A third point was that a number of the patients had had to work at some time with sugar. He did not feel he could go so far as Dr. White in saying there was no rash peculiar to these trades; but he felt that the case put forward on behalf of the bakers had been a good deal exaggerated. He believed that further investigations were being demanded.

Dr. L. A. PARRY said that he also had made experiments on this subject, in the person of a man, aged 63, who had suffered on so many occasions from bakers' eczema that he was put by the firm on to work in which he did not come into contact with the dough. He had not had any further attacks of the disease since that change was effected. This man was given two separate bowls of flour, in one of which was a preparation of ammonium sulphate and ammonium persulphate (salox) 1 in 4000, and in the other only flour and water. These were plastered on hand and forearm separately and left there for 15 to 30 minutes; and the same was done for six consecutive days, being removed by means of dry flour in the ordinary way. Neither arm at the end of that time showed any sign of irritation beyond a transient redness. A week later there was no trace of any abnormality in the man's skin.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

A MEETING of this Association was held on Oct. 14th, Miss M. CHADBURN, the President, being in the chair.

Dr. STENHOUSE WILLIAMS opened a discussion on

Clean Milk and its Production.

He pointed out that the milk industry had had little help or guidance from the medical profession in the problem of producing clean milk. Only those actually in the industry could really appreciate the difficulties and work out a solution. Since the establishment in 1913 at Reading of the National Institute for Research in Dairying, under the auspices of the Ministry of Agriculture, efforts had been made and had proved successful in interesting the local farmers in the ideals of the institute. The chief trouble in milk production was dirt, and its abolition must be viewed on an economic basis. Berkshire farmers had proved to be receptive of new ideas involving asepsis, and six or seven years ago it was generally recognised that a better quality of milk was worth a better price. After the war, and after a considerable struggle, the principle was maintained that farmers were allowed to charge more for cleaner milk. At present three grades of milk were available: certified milk, bottled by the farm; grade A tuberculin-tested milk, bottled by the dealer to whom it was delivered in sealed jugs; and ordinary milk. Certified milk formed only 2 per cent. of the milk supplied in New York at present, and it seemed unlikely that it would ever be possible in America or in this country to supply it cheaply enough to create a large market. Grade A tuberculin-tested milk, however, could be produced at a price of only 1*d.* per quart dearer than that of ordinary milk. In New York 2 per cent. of the milk consumed was consumed fresh and 98 per cent was pasteurised. An alternative to pasteurisation was to press for tested clean milk which could be drunk without treatment, and Dr. Stenhouse Williams said that he had made great efforts, with but limited success, to create a demand from doctors for such milk.

Mr. S. WHITLEY, chairman of the British Dairy Farmers' Association, emphasised the difference between the methods used in producing clean milk and those under which farming was carried on in the old days, and, indeed, was still carried on at farms where no effort had been made to raise the standard. The difference was comparable to that between modern aseptic operating rooms and the conditions under which Sairey Gamp worked. The steps taken to produce clean milk were as follows: First, the cowshed was kept clean, the cows were brought in, and the flanks washed and dried and udders washed and dried. The milker put on clean white overalls and washed and dried his own hands. Formerly, Mr. Whitley observed, cowmen used to wash their hands in the milk. Instead of wide-mouthed open milk-pails, covered pails were now used, a lip on the cover preventing dust which had settled on the cover from falling into the pail. The pail was then weighed, carried to the dairy where the milker without entering the dairy poured the milk into a tin receptacle. It was then cooled, churned, and sent in sealed cans to a retailer, who was also compelled to have a grade A T. T. licence. Surely these precautions were worth the 15 or 20 per cent. extra cost that the consumer had to pay. There was now keen competition among certain farmers to reduce the bacterial count in their milk. Milk consumption in this country was much smaller than in America, Canada, or Denmark. No single thing could benefit agriculture more than to persuade people to drink more milk. Last year over 160 farmers were producing higher grade milk, the supply then was much greater than the demand, but now more farmers were producing this milk, and Mr. Whitley understood that the demand was now greater than the supply. Many farmers were waiting only for the demand in order to start producing grade A milk.

Dr. AMY SHEPPARD asked what precautions were taken to keep the cows that did not react to tuberculin in health. A friend of hers had a herd of cows and took pride in the fact that two-thirds of them did not react; this was apparently a high proportion. Dr. Sheppard said that, in view of the large proportion of cows reacting to tuberculin, she herself would not trust untreated milk and would pasteurise all milk anyhow in country places. Would not keeping cows out of doors be a good plan?

Dr. WILLIAMS replied that cows were tested every six months and were inspected by a veterinary surgeon every quarter, and he considered that these precautions were sufficient. In many districts cows were kept out of doors.—Mr. WHITLEY said that there were certain disadvantages in keeping cows permanently out of doors, especially on wet land, but at least they could be kept in open yards and money could be spent on milking sheds instead of on cowsheds. As to the percentage of reactors many valuable results had been found. It was generally accepted that unless the udder was affected tuberculosis would not be transmitted through the milk. When the intestine or lungs was affected, however, the cow might be dangerous to other cows; in practice when a herd was once free it was found that only 1 per cent. or less than 1 per cent. of reactors were subsequently found.

Miss LOUISA MARTINDALE asked how the milkers' hands were cleaned to secure asepsis. Did they use rubber gloves, and was the same bucket and towel used by all the milkers?—Dr. WILLIAMS replied that sterile gloves were not used and hands were dried on ordinary towels. He did not think that any more stringent regulations were required.

Dr. R. GILLETT said that her children had been brought up on Moundsmere Manor milk and now refused to drink any other kind; presumably there was some noticeable difference in the flavour in really clean milk.

Mrs. FLEMMING, M.D., asked whether Dr. Williams would advise that those farmers who produce grade A milk should confine themselves to this kind of milk or whether they should aim at producing both kinds; now, apparently, cows which reacted to tuberculin tests were merely put into the other herd. Was this a satisfactory arrangement or should reacting cows b destroyed?

Dr. WILLIAMS said that at Reading reacting cows were killed. It was easy to adopt a high standard and say that this was essential, but he was not convinced that this was so. It might be economically very hard on the farmer and would interfere with supply of good milk, for the farmer might be unable to afford to produce it. In the old days, and in some places now, it was impossible to get reliable milk Now the public had an option and this might be a very good thing. In practice, if it were agreed that al reacting cows should be slaughtered, the farmer would have to be compensated and an economic basis would not then be maintained.

Dr. R. JORDAN asked whether, if the reacting cow was followed to the slaughter-house, active tuberculosis was necessarily found.

Dr. WILLIAMS explained that was one of the troubles unfortunately, it was impossible to foretell this.

Dr. CHODAK GREGORY was interested in the economi side of the question since children in London di not get nearly enough milk. If, indeed, grade A mil was only 1*d*. a quart dearer that would not be bad but surely it was a good deal more than 1*d*. a quar dearer in London?

Dr. WILLIAMS said that grade A milk could b bought in London at all prices. At Lord Rayleigh' dairies it could be bought for 2*d*. more per quart at other places up to 50 per cent. more. In hospital and welfare centres a start might be made in creatin a demand which would bring down prices. In answe to the Chairman, he said that St. Bartholomew' Hospital was supplied with grade A milk.—In answe to a question whether this hospital was satisfied wit the keeping qualities of this milk, Mr. WHITLE replied that some complaints had been receive indirectly. On investigation it had been ascertaine that the milk had been kept too hot, had reached temperature of 74° F., whereas it should be kep at 60° F. It must always be realised what an exceedingly delicate product milk was.

Dr. I. LANE spoke of conditions in Sydney and aske whether gastro-enteritis was less prevalent at Readin than elsewhere in this country.—Dr. WILLIAMS coul not give information on that point, but referred her t the local welfare centres.

Dr. ENID MOORE had been feeding her baby o certified milk, but was concerned in the summe because 36 hours elapsed between the time of milkin and the time of the 6 o'clock early morning fee This seemed a very long time. She had been advise by her dairy to use instead their nursery milk whic was pasteurised on collection. This advice was to th economic disadvantage of the firm, since certified mil cost 1*s*. 2*d*. and nursery milk only 8*d*. per quart as a matter of fact, the cream contents of the certifie milk was less than that of the nursery milk. She di not think that inspection every three or six mont was sufficient to guarantee that the cows had not bee infected between the inspections. She asked wheth Dr. Williams would recommend consumers to pasteurise certified milk if 36 hours were to elapse betwee milking and consumption.—Dr. WILLIAMS replie that a high cream line was proof neither of vice n virtue in milk. He did not think it was necessary t pasteurise certified milk under the circumstanc mentioned.

Dr. A. HUTCHINSON spoke of the great difficulty i obtaining grade A milk in certain London distric and of the great variability of prices. What pri should be quoted for mothers as reasonable?—D WILLIAMS said that the price ought not to be more tha 2*d*. per quart more than ordinary milk, but there wa no law preventing dairymen from charging what the could get.

Dr. E. CASSON thought that the distribution by mot lorries had worked so well during the railway strik that perhaps a plan could be devised to continue th system.—Dr. WILLIAMS said that a solution to th problems of distribution had not yet been found.

Reviews and Notices of Books.

EXT-BOOK OF PATHOLOGY.

By ROBERT MUIR, M.A., M.D., Sc.D., F.R.S., Professor of Pathology, University of Glasgow; Pathologist to the Western Infirmary, Glasgow. London: Edward Arnold and Co. 1924. Pp. 774. 35*s.*

A TEXT-BOOK of pathology by a teacher of the minence and experience of Prof. Robert Muir must ecessarily have a much wider appeal than to the tudent for whom it is primarily intended. In articular, other teachers of pathology will read it ith interest not only for its subject-matter but also ecause it reveals the point of view of one of the cknowledged leaders of his profession. For, as the uthor states in his preface, pathology has become so xtensive that a selection of subjects is necessary if students' text-book is to be kept within reasonable mits; and it is in this selection, this choice of what leave out, that an author's professional philosophy laid bare.

As might have been expected, Prof. Muir's book is dmirably conceived and well balanced. It deals hiefly with the structural changes in disease, since it in these that the whole basis of pathology must lie; ut the experimental and chemical sides are not eglected, and the effects of morbid lesions upon unction are constantly insisted upon. Such subjects s systematic bacteriology, parasitology, tropical iseases, diseases of the special senses and of the kin are not specifically treated; and no more space han is absolutely necessary is devoted to congenital bnormalities. The first 200 pages are devoted to eneral pathology, to disturbances of nutrition and f the circulation, inflammation, repair and hypertrophy, infection and immunity, and tumour formaion. The rest of the book is concerned with special r systemic pathology, the results of disease processes n the structure and function of individual organs. nasmuch as there are 433 figures included in the text must be obvious that a good deal of condensation as been necessary, and yet this is not apparent. he author, knowing what he wishes to say, says in the simplest language without circumlocution. hough helpful possibilities and theories are adequately iscussed, he has little time for vague hypotheses; e is chiefly concerned with facts, and he does not esitate to admit when these are insufficient for a rue understanding of the subject. It is probable that any of his readers would have preferred a wider resentation of many subjects, for the author's ndividual opinion on debatable points and his riticism of work still in the making would have been nvaluable. Guidance is badly needed in the interpreation of much of the modern work, that, for example, n infection and immunity. But such elaboration ould have been beyond the scope of the book. t is hardly necessary to say that Prof. Muir's teaching beyond reproach. In one or two minor instances, n his description of Paget's disease of the nipple, r example, it may be that he will be found to differ om other authorities; but for the most part his octrine is as sound as its presentation. A word must be said about the illustrations. With a few xceptions, these are photographs, and many of them re exceedingly good. The microscopic fields illusrated are small and often of low magnification, so has been possible to obtain perfectly clear and atisfactory figures. And the same may be said of he reproduction of naked-eye specimens. But there re illustrations—Nos. 16, 275, and 284, for example—hich the student will find it difficult to interpret, nd we could wish that more use had been made of rawings.

Prof. Muir has written a book which will, we redict, have an immediate success. The general ractitioner who desires to keep abreast of modern athological teaching cannot do better than turn to it; while the student will find it not only a safe guide to success in examinations, but a stimulating presentation of a subject upon which his final studies must be founded.

MASSAGE OF THE HEAD, FACE, AND NECK.

By OLIVE F. SANDS, Registered Member, Chartered Society of Massage and Medical Gymnastics; Masseuse to Savernake Hospital, Marlborough. London: The Scientific Press, Ltd. 1924. Pp. 62. 1*s.* 3*d.*

THIS little book is one of the pocket guide series of the Scientific Press. It is written by a qualified masseuse for the help of those who follow the same profession. For them the details of technique given in the first chapter should be unnecessary, while they are not sufficiently full to be of material assistance to others. The conditions dealt with in the manual are those for which massage of the head and neck is generally employed; the use of massage in the relief of insomnia might well find a place. It is a little unusual to find torticollis referred to as a painful condition, and although injury to muscle at birth is mentioned as a cause of the condition, no special description is given of its treatment. Massage twice or three times a day for 15 minutes seems to us excessive for a child. On the whole, however, the advice given is sound, and if a masseuse should find herself confronted with a case which she has been told to treat without specific instructions, and is in doubt as to how to proceed, she will here find suggestions which will guide her at least in safety.

MECHANO-THERAPEUTICS.

Collected Papers on Mechano-Therapeutics. By EDGAR F. CYRIAX, M.D. Edin. London: John Bale, Sons and Danielsson, Ltd. 1924. Illustrated. Pp. 472. 12*s.*

Dr. Cyriax has made a valuable contribution to the library of physical therapeutics by collecting his numerous communications to the medical press into one volume. He presents us with 65 original papers written in three different languages, and he gives a list of 16 other articles which are not here reproduced. The range of ground covered is extensive. The first 17 papers deal with treatment of the nervous system, the next 22 with bones and joints, 4 are devoted to anatomical study, 11 to the internal organs, while the remaining 11 are on various topics, including 4 on various aspects of work done during the war. The last paper on some points of priority in mechano-therapeutics is of interest, since it shows clearly that the names attached to certain recognised treatments are those of imitators rather than of originators. A full bibliography is attached to each paper.

The book has two serious drawbacks: First, the almost inevitable fault of repetition; secondly, that reference from one paper to another is made by name and not by reference to page or chapter. In this matter the index is of service, but even so, it is at times a matter of considerable labour to find the reference for which one is searching. The average medical man glancing through the list of contents and finding physical treatment advocated in the treatment of acute pleurisy, pneumonia, and diabetes, might feel disposed to lay the book aside as being too revolutionary to merit further attention. He will also find it difficult to accept the possibility of the displacement of the inter-vertebral discs, although a growing number of medical men place credence in minor displacements of the vertebræ and the symptoms which are alleged to arise therefrom. The time has not yet come when these things will receive general acceptance. Yet the work done on these lines by Dr. Cyriax has, in his hands, met with a considerable measure of success, and the need is for other workers to ascertain whether the claims made can be justified in their own experience. The first section of the book dealing with the treatment of the central nervous system must inevitably meet with antagonism, as electrical treatment of flaccid paralysis will find many advocates, while Dr. Cyriax would have us rely on physical treatment. Scanty reference is made to the value of splintage in these conditions. But a priori considerations should not be allowed to detract from the value of researches into the little known ways of the sympathetic nervous system ; if, for example, the victim of chronic constipation can really be relieved by restoring the function of the coccygeal ganglion, all other remedies must be at fault.

Dr. Cyriax is an enthusiast. It may not be possible to accept unquestioned all his observations, but if the publication of this book can inspire others to follow his lines of investigation, even if it is only to prove or disprove the results of his work, a definite advance will be made in medical knowledge.

HISTOLOGY OF TUMOURS.

An Introduction to the Histology of Tumours. By HAROLD A. HAIG, M.B., B.S., D.P.H., Lecturer in Pathology and Bacteriology, Welsh National School of Medicine. London: Henry Kimpton. 1924. Pp. 124. 7*s.* 6*d.*

IN his preface the author states that his book is designed for the use of students and working pathologists and, furthermore, that it has been his aim to avoid controversial matter. Unfortunately, in the present state of knowledge concerning the nature of tumours, the only refuge for the author who would avoid the introduction of conflicting views in a work of this sort is dogmatism, and dogmata are dangerous food for students, while it is to be hoped that "working pathologists" will have nothing to do with them. The descriptions of the commonly recognised and more or less intelligible tumours are clear and concise and should prove of value to the student. In the case of the more obscure neoplasms, such as those originating in the testis, the absence of any critical consideration of the various views as to their nature and origin detracts somewhat from the value of the work ; an important group of new growths, the "mixed tumours" of Wilms, almost entirely escapes notice. However, the student will find much information clearly expressed in this inexpensive little manual, and will doubtless find it a help in the study of a difficult subject.

PEDIATRICS.

Physiopathologie de l'appareil digestif du nourrisson. By ENRIQUE SUNER, Professeur de Clinique infantile à la Faculté de Madrid. French translation by Dr. MATHÉ. Paris: Masson et Cie. 1924. Pp. 92. Fr.10.

THIS little book, which is introduced to French readers by Prof. Nobécourt, presents an account of the infant's digestive and metabolic processes in health and disease and of the essential principles of infant feeding. The section dealing with physiology is admirable, the work of recent years being clearly summarised in a small space. The metabolism of albuminoids is fully described, with special reference to Hamburger's work on absorption of colloids ; considerable attention is also paid to basal metabolism and calorimetry. Pathology is dealt with rather less fully than physiology, but the subject is presented clearly and readably. The author's standpoint is roughly similar to that of Prof. Nobécourt ; he does not subscribe to the views of Czerny or Finkelstein, but regards protein as a common source of digestive disturbance. The chapters on infant feeding will not meet with such general agreement as those on physiopathology. The author himself emphasises the effect of dissimilar climatic conditions on dietetic requirements, and this factor must be borne in mind. He gives the twelfth month as the normal time for weaning, and recommends the addition of starch to the diet of a breast-fed infant from the sixth month. The list of maternal indications for weaning is not particularly helpful, and contains the statement that mitral stenosis is usually congenital. The mixture which the author recommends for artificial feeding has a fat-content distinctly below that of human milk.

This book contains a considerable amount of valuable material ; the addition of references would render it a really useful introduction to the study of infant metabolism.

Examination of Children by Clinical and Laboratory Methods. By ABRAHAM LEVINSON, B.S., M.D., Associate in Pediatrics, Northwestern University Medical School, Chicago. London: Henry Kimpton. 1924. Pp. 146. 18*s.*

IN this book the author has attempted to bring together all the procedures which may be employed, either at the bedside or in the laboratory, for the diagnosis of the diseases of children. Inasmuch as many of these procedures are the same both for children and for adults, it is inevitable that a work of this sort should encroach largely upon the domains of the ordinary text-books of clinical pathology. There are, indeed, sufficient differences in the interpretation both of clinical signs and of laboratory tests in children as opposed to adults to offer ample justification for the production of such a work, but it is the actual procuring of specimens of one sort and another for assay which offers the most serious difficulty in the examination of children from the laboratory standpoint. Dr. Levinson's descriptions of the technique for procuring samples of blood, urine, and so forth from babies form by far the most valuable part of the book and would alone constitute it a most useful aid to the pediatrist.

DIFFERENTIAL DIAGNOSIS.

Vol. II. Presented through an Analysis of 317 Cases. By RICHARD C. CABOT, M.D., Professo of Medicine and Professor of Social Ethics at Harvard University ; formerly Chief of West Medical Service at the Massachusetts General Hospital, Boston. London and Philadelphia W. B. Saunders Company. 1924. Pp. 709. 42*s*

WE recently had occasion to express appreciation of Dr. Cabot's book on "Physical Diagnosis," and commented on its value to the student. The present book is the second volume of a work in which cases illustrating the significance of various major symptoms are discussed in detail. There may not be a large public for such a work in this country, but to the medical man who perforce lives isolated from centres of medical education, there can be few better ways of reviving and increasing his knowledge than by reading such a book in which physicians and surgeons of acknowledged authority give their opinions on particular cases. The descriptions of the cases are sufficiently well done to bring the picture of the patient clearly into mind, and the diagrams and charts which illustrate the volume are well reproduced.

DOSES AND SOLUTIONS.

A Text-book for Nurses and a Reference Book fo Physicians and Nurses. By C. E. GARNSEY Instructor in Anatomy, Dosage and Solutions, &c. in the Washington Sanitarium and Hospita Training School for Nurses, Washington, D.C London and Philadelphia: W. B. Saunder Company. 1924. Pp. 111. 5*s.*

IT is somewhat difficult to determine the use of thi small book on dispensing. In this country at any rat the nurse does not—in her usual vocation—need th information it gives. It may be useful to the docto who dispenses his own medicines if he has forgotte his elementary mathematics and will take the troubl to find what he wants in it. Probably it will be mos useful to a class not mentioned in the dedication— namely, the doctor's unqualified dispenser, for i ffords such a person two aids, some information bout drugs and numerous lessons about the applied nathematics of the dispensary. The working out f the arithmetical problems which meet the dispenser s given in minute detail, and numerous questions re set to which answers are given later in the ook. Simple medical terms are explained, drugs re classified according to their actions, prescriptions re explained, but the dominating feature is the vorking out of problems of quantities—often omewhat intricate—which the prescription sets the lispenser.

JROLOGY.

Die Endoscopie der männlichen Harnröhre. By Dr. ALOIS GLINGAR. Vienna: Julius Springer. 1924. With four plates. Pp. 72. $1.70.

THIS is a brief and business-like monograph on ndoscopy of the male urethra. The instruments used or endoscopy both with air distension and with rrigation are described, and suggestions are made as o their clinical use. Detailed descriptions are given f the appearances of the urethra in normal and in liseased conditions, as seen by both methods. The lescription of the pathological changes in the deep urethra is particularly good. A short account is given f the various manipulations and operations which an be carried out endoscopically, and the whole is llustrated by a first-rate series of plates.

The book is essentially practical, and is plainly the work of an expert. It can be warmly recommended o all who practise this branch of surgery, and those who do not read German will find the book useful for the sake of the plates.

DIGBY'S MIRACLE.

By FRED. E. WYNNE. London: Herbert Jenkins. 1924. Pp. 310. 7*s.* 6*d.*

Dr. Digby is by training and inclination an experimental physiologist, and by circumstance a village practitioner, whose heresies preclude popularity. His special knowledge finds little scope until, called to the bedside of a paralysed girl whose patience under affliction has given her the status of a village saint, he is able to confirm his suspicions of her integrity by eliciting normal electrical reactions from her muscles. Her exact mental state, whether hysteria or conscious malingering, is not quite clear, but it is the circumstances of her cure rather than the pathology of her condition that are incidental to Dr. Wynne's intriguing story. For, to save the patient's face and also—a less worthy motive—to advertise the village for his own advantage, this enterprising fellow, young Digby, organises a miracle, arranging with the girl to have a vision guiding her to the curative waters of an old well. His punishment is not light: he has attracted this erotic, ill-balanced patient, who attempts to compromise him, and moreover his real affinity is repelled when she learns the source of the first of the series of faith-cures which are making the village famous. Flitting vaguely through the book is a rather prolix unworldly peer, who criticises nothing—not even the breeding of a professional man who addresses him repeatedly as "your lordship"—but quietly restores peace all round by having the stream of water deflected from the "holy" well.

The idea underlying the novel is excellent, and as a good story it should appeal to a wide and varied public. Those only will be disappointed who would wish to see the psychological problems involved more clearly defined and discussed, and the characters investigated more searchingly. A subject worthy of Henry James is wasted as the plot of a breezy novel, however absorbing; but it is probably just as a relaxation from socio-medical problems that the medical officer of health for Sheffield turns to the writing of light novels. Those who enjoyed the "Mediterranean Mystery" will find its successor no less entertaining.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

XXI.—MEDICAL ASSISTANTS.

By JAMES NEAL, M.R.C.S. ENG.,
GENERAL SECRETARY OF THE MEDICAL DEFENCE UNION.

Quamdiu se bene gesserit.

Passing of the Unqualified Assistant.

LESS than half a century ago it was a common practice for a registered medical practitioner to employ one or more unqualified persons as assistants in the work of the practice. These unqualified assistants were frequently left in sole charge of medical practices, although possessing little or no professional knowledge, and so greatly was this custom abused that in 1893 the General Medical Council passed a resolution to the following effect:—"That the Council record on its Minutes for the information of those whom it may concern, that charges of gross misconduct in the employment of unqualified assistants, and charges of dishonest collusion with unqualified practitioners, in respect of the signing of medical certificates required for the purposes of any law or lawful contract, are, if brought before the Council, regarded by the Council as charges of infamous conduct under the Medical Act." This pronouncement was followed in 1897 by the following Warning Notice:—

> "Whereas it has from time to time been made to appear to the General Medical Council that some registered medical practitioners have been in the habit of employing as assistants in connexion with their professional practice persons who are not duly qualified or registered under the Medical Acts, and have knowingly allowed such unqualified persons to attend or treat patients in respect of matters requiring professional discretion or skill; and whereas in the opinion of the Council such a substitution of the services of an unqualified person for those of a registered medical practitioner is in its nature fraudulent and dangerous to the public health, the Council hereby gives notice that any registered medical practitioner, who is proved to have so employed an unqualified assistant, is liable to be judged as guilty of 'infamous conduct in a professional respect,' and to have his name erased from the Medical Register under the 29th section of the Medical Act, 1858.
>
> "Further, in regard to the practice commonly known as 'covering,' the Council gives notice that any registered medical practitioner, who by his presence, countenance, advice, assistance, or coöperation, knowingly enables an unqualified or unregistered person (whether described as an assistant or otherwise) to attend or treat any patient, to procure or issue any medical certificate or certificate of death, or otherwise to engage in medical practice as if the said person were duly qualified and registered, is liable to be judged as guilty of 'infamous conduct in a professional respect,' and to have his name erased from the Medical Register, under the said enactment.
>
> "But the foregoing notices do not apply so as to restrict the proper training and instruction of bonâ-fide medical students or the legitimate employment of dressers, midwives, dispensers, and surgery attendants, under the immediate personal supervision of registered medical practitioners."

From this time the unqualified assistant has gradually disappeared, though for some years the regulations of the General Medical Council permitted a bonâ-fide medical student to spend six months of his final year as a pupil to a registered practitioner. Little, if any, advantage was taken of this permission, however, and in 1906 the General Medical Council withdrew the recommendation.

In these days any assistant in a medical practice must himself be a registered medical practitioner, and the fact of registration should be verified in every case. The greater number of assistants are comparatively newly qualified men, who, after holding various resident appointments in hospital, are anxious to acquire an insight into the details of medical practice before setting up on their own account. Certainly there is no better way of completing one's medical education, but a year or two spent in this way will suffice, though many who start their professional careers as assistants are compelled from want of capital to remain in that position much longer before they are able either to buy a partnership or practice, or to set up on their own account. An assistancy with a view to partnership should only be entered upon when there is a definite agreement, signed by the principal, to offer the assistant a partnership at a definite date on terms, the more important of which should be specified in the agreement. I have referred to this point in a previous article, but it may be well to repeat the warning here.

The Contract: Law and Custom.

The legal relationship of principal and assistant in a medical practice is that of master and servant. It necessarily follows that the assistant becomes the agent of the principal for certain purposes, and that the ordinary principles of agency apply. The contract should in every case be made in writing, however short the period of the engagement, and should include the following principles drawn up by the British Medical Association :—

1. The assistant to give diligent and faithful service.
2. The assistant to give his whole time and attention to the practice under the direction of the principal.
3. The assistant to receive from the principal periodic payment for his services.
4. The assistant to keep just accounts and pay over to the principal all moneys received on behalf of the practice.
5. Provision for a holiday for the assistant.
6. Provision for the determination of the agreement.
7. Period for the duration of the agreement.
8. A restrictive clause as to practice during and after termination of the agreement.
9. A provision that both the principal and the assistant should be members of one of the Medical Defence Societies during the whole period covered by the agreement, and for the settlement of disputes by arbitration.
10. That if the principal requires the assistant's name to be put upon the insurance panel the assistant must agree that either the assistant shall not accept any insured person other than in the name of, and on behalf of, the principal, or if any insured persons are accepted in the name of the assistant he shall take every possible means to ensure the transfer of those persons to the list of the principal on the termination of the agreement.

The agreement must bear the proper stamp, and should be drawn up by a solicitor who has been fully instructed as to the requirements of the case. Where no contract exists, or the agreement does not specify what notice shall be given to determine the contract, the following customs have been held to prevail in the profession :—

1. In the case of a permanent assistant, engaged nominally for the year, where the salary is paid weekly, the custom is to give and require a month's notice.
2. An indoor assistant, or an outdoor assistant living in lodgings, or in a house furnished and provided by the master, may be dismissed, at any time, by a month's notice, or on the payment of a month's salary.
3. An outdoor assistant, living in lodgings, or in a house furnished and provided by himself, by the wish, or with the consent of the master, may be dismissed, at any time, by a three months' notice, or on payment of an equivalent salary.
4. Where an outdoor assistant, at the suggestion of the master, takes an unfurnished house, upon a yearly tenancy, terminable by a quarter's notice, at any quarter-day, and furnishes such house himself, it is customary for the master to give a three months' notice, terminating on the next ensuing quarter-day.
5. Where the master provides the house or rooms for an outdoor assistant, and the assistant provides the furniture, it is usual to give a three months' notice.

Relation between Principal and Assistant.

An assistant is legally bound to obey all reasonable and lawful orders of his principal, and may be dismissed without notice for wilful disobedience, gross misconduct, negligence, incompetency, or permanent disability through illness. The contract of service is dissolved by the death or bankruptcy of the principal. The principal must indemnify the assistant from the consequences of all lawful acts done in pursuance of his duties. This does not apply to the ordinary risks of a medical practice—e.g., the danger of attending infectious diseases. In law the principal is responsible for the consequences of any act of his assistant performed in the course of his employment and duty, this being the ordinary responsibility of the principal for the acts of his agent. But the assistant also is responsible in law for his own acts, and the aggrieved party has the right to select whether he will bring the action against the principal or against the assistant, or against both.

It is most desirable that both the principal and the assistant should be members of one and the same defence society. The two defence societies in this country, although coöperating in all matters in which they have a joint interest and concern, maintain an entirely independent position, and a few years ago in a joint letter to the medical press it was pointed out that membership of either society was purely personal, so that no member would be protected against an action brought against him in respect of an act of his partner, assistant, or locum-tenent, unless such partner, assistant, or locum-tenent were a member of the same society as the principal.

Remuneration.

The remuneration of an assistant varies in different practices according to the amount of work to be performed, and according to whether his board and lodging are paid for by himself or by his principal. Not infrequently a commission is paid in addition to the salary, either on midwifery cases attended, or in some instances a percentage is given on all receipts of the practice over and above a stated amount, to encourage the assistant to make every effort to increase the takings beyond that figure. An assistant rightfully discharged has no claim against his principal for salary for the broken period of service. When an assistant is engaged by a firm of partners, any partner has a right to terminate the engagement, so long as his action is ratified by the other partners. But if one partner tells the assistant to remain, the latter will be within his legal rights in disregarding the notice to leave. A principal can recover fees for attendances given by an assistant, so long as the services of the assistant have been accepted by the patient.

In the absence of any specific agreement to the contrary, all professional fees paid to an assistant, including fees for notification of infectious diseases, for attendance at inquests and court cases, and for performing post-mortem examinations on the direction of a coroner, belong to the principal. It is customary for the principal to pay the travelling expenses incurred by an assistant for the purpose of taking up his appointment, and for the assistant to pay his own expenses when he leaves.

Restrictive Clause.

Assistants are obtained by personal recommendation, by advertisements in the medical journals, and through a medical agency. In the latter case the agency accepts a certain responsibility, and should be informed at once if the assistant should prove unsatisfactory. The restrictive clause which it is now customary to introduce into an agreement with an assistant is of great importance. The radius within which and the length of time during which the assistant shall be debarred from practising in the locality vary according to the class of practice and the nature of the district. The prohibition is usually less severe than in the case of a partner, but should be sufficient to protect the principal from serious opposition. On the other hand, it must not be made wider than is reasonably necessary for this purpose, or it might be declared null and void, as contrary to the public interest. It should particularly be observed that the restraint is not removed by the death of the principal or by his retirement from practice.

THE LANCET.

LONDON: SATURDAY, OCTOBER 25, 1924.

AN EXEMPLARY PENALTY.

The matters at issue between the insurance medical service and the approved societies having been settled for the immediate future, the annual panel conference on Oct. 16th[1] was of a more domestic character than for some time past. It was possible at the beginning to make arrangements for the regular holding of a social dinner at the time of each annual gathering, and at the end to offer a well-earned token of gratitude to Dr. H. G. Dain, who is retiring after having piloted the conference through many stormy sessions. Much of the time was occupied by deciding what evidence, and in what form this evidence, should be presented to the Royal Commission on National Health Insurance, which held its second meeting on Oct. 15th at the Ministry of Health, and was to meet again on Oct. 23rd. The Commission, we understand, decided that the sessions at which oral evidence is taken will be held in private, a verbatim report of the evidence to be published within about a fortnight of each meeting. The atmosphere of the conference was, indeed, so calm that it was deemed advisable to give warning of possible squalls ahead. The defence fund, which has only yet reached a bare quarter of the £250,000 contemplated by its initiators, is increasing, but increasing slowly, doubt being present to many minds whether, with the capitation settlement and the Royal Commission appointed, its existence was any longer justified. Dr. Brackenbury pointed out with the wisdom of an experienced fighter that not only did one never know, but that a large sum of money at the back of them is an untold comfort to those on whom falls the duty of conducting ticklish negotiations.

The one really absorbing interest at the panel conference was the £1000 fine inflicted by the Ministry of Health on two panel practitioners charged with accepting fees for medicines supplied to insured persons in contravention of the terms of service. The committee appointed by the Ministry to inquire into the circumstances consisted of Mr. E. H. Tindal Atkinson, Barrister-at-Law (chairman), Dr. Dain, and Dr. Alex. Forbes, and their report was made just a year ago. It is unnecessary to summarise this report here, for the material portions of it have just been printed in a document issued by the Stationery Office.[2] Stated in general terms, the complaint submitted for inquiry was not merely the illegal acceptance of fees, but the encouragment of the belief that drugs or medicines provided by the insurance committee were not as efficacious as those which the panel doctor could supply, such an attitude being regarded as calculated to have an effect derogatory to the medical service. The sum of money involved in the transactions amounted to a total of about £60, the separate items of medicine being charged at the rate of 3*s.* 6*d.* per bottle or 3*s.* for cash. Only in three cases was the committee satisfied on the evidence that there was anything in the nature of direct suggestion from the respondents to patients that the latter should order and receive private medicine. But the committee found that there did exist among a certain proportion of insured persons in the district an impression, which the respondents were not careful enough to combat, that medicine supplied under insurance prescriptions was inferior and less efficient than that which doctors could themselves directly provide. There was no question whatever of concealment; the books were placed freely at the disposal of the inquiry, and all relevant documents were frankly disclosed. Acting on this report the Ministry decided not to remove the doctors from the medical list but to withhold a sum of £1000 from the supplementary grant. Subsequently the respondents applied to the High Court for the decision to be quashed on the technical ground that the insurance committee had made representations in respect of one of them without first directing an investigation by the medical service subcommittee, but this claim was not upheld. The Insurance Acts Committee has continued to press the Ministry to reconsider the penalty, but apparently the last word has been said and the decision is final. With these facts in view a motion was brought forward at the conference by the medical committee of the area, suggesting that the vindictive action of the Ministry in this case had disclosed a position of such danger to panel practice that in the event of its repetition immediate steps should be taken to send in notices of resignation. The chairman of the local committee expressed a doubt whether such a fine could be regarded in the nature of a penalty at all; he felt that so large a sum would not have been awarded against the doctors by a court of law, and that the penalty had awakened among panel doctors generally a feeling of distrust of the Ministry which could only be detrimental to the service. The decision has apparently led to a reawakening of the demand, repeatedly made at panel conferences for many years but which lately had practically died away, that decisions of the Ministry should be subject to appeal before some judicial tribunal. The conference, however, with commendable restraint decided not to brand the action of the Ministry as vindictive but to express its opinion that it was contrary to the principles of English justice for the Ministry to assume offences over and above those proved at the inquiry and to inflict any penalty in regard to such unproved offences, and further to protest against the invitation of the Ministry to the insurance committee to revise conclusions reached by that committee after inquiry in accordance with the regulations.

Apart altogether from the question of equity, the case gains greatly in interest from the fact that, according to their representatives at the conference, practitioners in South Lancashire do hold strongly that the medicine prescribed by them is actually more valuable to the patient than medicine in which the patient has no confidence. Their representatives were equally certain that all the practitioners in the area are desirous of carrying out strictly the wording of their regulations which forbid them to make a charge for medicine to patients on their list. The difficulty therefore remains unsolved. Doctors in Lancashire, no more than in other industrial areas, try to induce patients to take their physic; it is the patients themselves who demand the physic and who insist on paying for it. The inquiry committee had to admit that there was a custom prevalent in the county, as well as in other districts, whereby the ordinary patient regarded the supply of medicine and payment for the same as a matter of greater importance in his cure than the services rendered by his doctor by way of attendance. In these days little enough may remain of the bedside manner in its widest sense as an asset in contract medical practice; but here is an instance in which a natural belief in the value of the doctor's physic must be dispelled—and dispelled to the disadvantage of the patient—by the practitioner who accepts his statutory duties under the Insurance Acts. It is a psycho-physical problem of no little medical interest, and one which cannot be disposed of by an exemplary fine.

---

[1] A report of the conference appears on p. 873.

MENTAL HYGIENE AND WAR SERVICE.

THE occurrence of mental disorders on a large scale during the war found us to a great extent unprepared, and even those psycho-pathologists who were awake to the situation did not foresee that one legacy would be the presence of large numbers of ex-soldiers mentally unfit to take their place in the economic life of the State. These disorders were mainly of the kind called minor psychoses or psychoneuroses, and among the cases were found a high percentage, ranging from 50 to 80, with a history of pre-existing psychoneurotic symptoms. Service experience obviously exacerbated morbid states which would have remained comparatively harmless under ordinary conditions. It is not possible to say what proportion of pensioners belong to the group, since the official invaliding disability often gives no indication of the true nature of a man's disorder; but the proportion is a high one and the resulting social inefficiency is serious. Employers find that these men offer a greater problem than ex-soldiers with physical disabilities, and one hears from the men themselves complaints of an unfavourable discrimination which appears unjust and yet is sometimes inevitable. Economic stress on the one hand and a pension on the other operate unfavourably in presence of a condition that primarily arose as a failure of mental adjustment and still maintains that character. The popular belief in a physical foundation for the trouble, a belief fostered by the unfortunate phrase "shell-shock" and to a less extent by the word "neurasthenia," does not simplify the problem of the psychoneurotic pensioner. Events in America have followed a similar course, and an article by Lieut.-Commander R. F. SHEEHAN on Military Mental Defect[1] formulates conclusions with which workers in this country will be in almost complete accord. He finds that psychoses, such as dementia præcox and manic-depressive states, did not occur during the war with greater frequency than in peace, that dementia præcox was the most prevalent psychosis, as might be expected from its age incidence, and the group comprising the psychoneuroses and so-called border-line states was productive of the most damage. Not only during the war activities, but after the cessation of hostilities, they made up the largest class receiving aid from the Government. Dr. SHEEHAN deems it possible to exclude, by careful psychiatric examination, a large number of those who would develop symptoms under the pressure of war activities, and the suggestion should be read in conjunction with another article in the same journal which refers with pride to the results of an organised effort to exclude from the army those men in whom the presence of an early tuberculosis seemed likely. Dr. SHEEHAN points out the difficulties in handling psychoneurotic pensioners, and that the resistance to treatment characteristic of the condition is often fostered by a well-intentioned but misdirected interest, based upon an erroneous conception of the mechanisms underlying the production of the symptoms. Such difficulties are familiar on this side, and our Pensions Ministry is faced by the dilemma that it is the duty of the country to help, by pension and treatment, those who broke down through a combination of predisposing tendencies and the stress of war—a stress sometimes as great as man was ever called upon to endure—and that at the same time the patients must be encouraged towards a rehabilitation of morale, towards a renunciation of the feelings of dependence, and away from the use of the symptoms as a defence reaction against the difficulties of life.

◆

THE ELECTRONIC REACTIONS OF ABRAMS.

DR. ALBERT ABRAMS, of San Francisco, originator of the system of diagnosis and treatment by means of the so-called electronic reactions, died at the beginning of this year. His system lives after him. A few days ago the *Daily Express* reported a New Zealand case in which a woman was awarded £2000 damages against an Auckland doctor for "negligent treatment and false representation tending to needless delay and suffering before undergoing an operation elsewhere." The necessarily brief account from which we quote indicates that the patient was advised by two doctors to undergo an operation for cancer; she was treated instead by a practitioner who administered the Abrams treatment, and who is stated to have assured her that it would effect a cure in four or five weeks.

It happens that a full account of ABRAMS and his system is given in the *Scientific American* of last month. That journal, which conveys a variety of technical information in popular form, undertook a year ago, in response to repeated inquiries from its readers, an investigation of the diagnostic and curative value of electronic reactions. It appointed a committee with suitable qualifications, and it has now summarised the committee's conclusions. The investigators closely examined the Abrams instruments and technique; they saw the system at work, and they conducted a voluminous correspondence with practitioners and patients. The result, based on materials which we have no means of testing but framed in terms which we do not hesitate to accept, is a clear finding that the so-called electronic reactions of Abrams have no objective existence. The Abrams technique is declared to be "at best an illusion, at worst a colossal fraud." The summary contains a narrative of the evolution of the Abrams system, which is of human as well as medical interest. The story tells how the originator discovered that electrons were the real basis of life, the foundation of good or ill health. We hear of such instruments as the dynamiser and the reflexophone, invented for gathering, sorting, and tuning the electronic emanations from a blood specimen. Then comes the discovery of the percussive effect of the electronic waves or vibratory rates upon the human abdomen, with the subsequent claim to detect thereby cancer, tuberculosis, syphilis, and other pathological conditions in their incipiency before their symptoms can be observed by orthodox medicine. Electronic diagnosis told the patient's life-history from a drop of his blood. He pricked his finger, wiped the blood on a piece of blotting-paper, and posted the specimen to an electronist. The latter placed the specimen in the dynamiser, connected the apparatus up with a healthy young man or woman known as the reagent, and then made his diagnosis. The reagent responded to the vibratory rates in the blood specimen. If the patient had a toothache or a sore toe, the reagent, acting as the patient's proxy, had the same. The next stage was the invention of the oscilloclast, a machine for setting up electronic waves to break up or combat the harmful and destructive waves within the patient's body and thus restore him to a normal electronic balance. Fortunate in the publicity it received, the electronic reactions method advanced in popularity until, according to the *Scientific American's* estimate, in 1923 there were over 3500 electronic practitioners at work. If they did not all use the Abrams technique, most of them were using something like it. Patients began to ask for the Abrams treatment for which so much was claimed. Orthodox practitioners, tempted to give the public what it clamoured for, could take a 250-

---

[1] The Military Surgeon, Washington, D.C., October, 1924.

dollar four-weeks' course and emerge fully qualified. At first, it seems, Dr. ABRAMS intended to confine electronic practice to doctors with a M.D. degree. Presently the basis was broadened. Orthodox doctors found themselves in strange company. The local medical association declared against the electronic system. Unkind tricks were played upon electronists who were sent specimens of chicken blood and diagnosed them as the blood of men suffering from congenital syphilis, cancer, tubercle, and so on. Orthodox doctors who had strayed into this field had either to find their way back to orthodoxy or to flourish by unorthodox methods which were commercially the more successful in proportion as they were the less scrupulously employed.

Incredible claims were made on behalf of the Abrams system. He appeared in a San Francisco court prepared to determine the paternity of a child by the electronic diagnosis of a drop of blood. In the recent New Zealand case counsel for the plaintiff asserted that it had been claimed that the Abrams machine could diagnose any of more than 100 diseases and could cure them, and that it could tell a man's religion and predict the sex of an unborn child. If we discount this assertion as possibly warmed by the genial fervour of a forensic atmosphere, the *Scientific American* narrates scarcely less remarkable stories of Dr. ABRAMS finding himself able to make his diagnosis from a photograph or a lock of hair in place of a drop of blood. Possibly it was the journalists who encouraged him in these higher flights. If so, it is appropriate that our contemporary should have restored the balance. The story is a study in faith healing and human gullibility. One strange feature of it is the fact that there was a moment when the Abrams method received a not unflattering attention in unexpected places in this country.

THE FIRST SOCIAL EVENING AT THE ROYAL SOCIETY OF MEDICINE.

THE first social evening of the session took place on Thursday, Oct. 16th, when Fellows, members of Sections, and their friends were received by the newly-elected President of the Society, Sir StClair Thomson. At 9.30 the Barnes Hall was filled to overflowing to hear an illustrated lecture by Dr. W. T. Grenfell, of Labrador, on Medicine in a Corner of the Empire. The new President was in great form throughout the evening, and his remarks in introducing Dr. Grenfell were of a gaiety to which no report can do justice. He admitted to a considerable feeling of awe at finding himself the sixtieth President in the 120 years since the foundation of the Society. Among those who had preceded him in the chair were Addison and Bright, who have given their names to well-known diseases, while he had reached his present age and had not yet discovered a good, killing, serviceable disease! Of surgeons who had held that office before him he instanced Abernethy, Astley Cooper, Benjamin Brodie, and Sir James Paget; his own position there he owed greatly to the fact that he represented the specialty to which he had devoted a life-time. Only once before had a specialist occupied the chair, in the person of Sir Francis Champneys. He felt very proud at being chosen as the first ophthalmic specialist to break the long chain of surgeons and physicians who had followed one another since the year 1805. The Society, which now numbered some 5000 members, was, he said, carried on by the active hon. secretaries, Mr. W. Girling Ball and Dr. H. L. Tidy, who had just taken the place of Dr. A. M. H. Gray after five years' strenuous service. In presenting the lecturer, Sir StClair Thomson reminded his audience that Dr. Grenfell was an old Marlborough boy, an old Oxford Rugger Blue, a past house surgeon to Sir Frederick Treves, that he once looked after the "elephant man," that he was an F.R.C.S., and also qualified as a master mariner. A report of Dr. Grenfell's lecture will be found on p. 891.

Annotations.

"Ne quid nimis."

OCCUPATIONAL DISEASES OF MINING.

THE coal-mining industry, although the general mortality of its workers is not high, suffers more than any other industry from occupational diseases which are subject to compensation. Foremost stands miners' nystagmus with 4091 new cases in 1922; second comes "beat" knee with 1721, third is "beat" hand with 1138, while "beat" elbow with 200 new cases is only just behind industrial lead poisoning with 247. The four first-named diseases essentially concern coal-miners. Nystagmus has already been the subject of two reports made by a special committee of the Medical Research Council. Now two members of that committee discuss the three "beats" in a report which has just been issued.[1] The prevalence of these diseases is stated; their causation is debated; their clinical characteristics are described; and means for their prevention and treatment are advocated. The disease in each case is a subcutaneous cellulitis of the part affected originating from trauma, chronic or acute, the result of work. The vernacular name "beat" indicates of itself that these diseases are not new things; nystagmus, on the other hand, which is a comparatively recent trouble associated with deficient illumination, presents a contrast in possessing no such popular designation.

The report is of interest not merely for the amount of useful information it contains, but because it sets forth the difficulties often associated with any attempt to reduce to statistical proof the causative influences concerned with occupational diseases. An effort is made to disentangle the possible effects of getting hard or soft coal, of working in wet places or in thin seams, of hand or machine getting, of depth of workings and of temperature; some support is found for the accepted opinion that, owing to the posture assumed when undercutting coal (of which good pictures are given), work in thin seams, especially if wet, tends to cause beat knee and also beat hand, which latter disease is also influenced by the hardness of the coal. The evidence gathered from each individual case, and from practitioners working in colliery areas, proves to be more valuable than records comparing the incidence of the diseases with the conditions prevailing on the different coalfields. In Somerset and the Forest of Dean coal is drawn on toboggans from the face by human traction; on these coalfields the workings, limited by the thickness of the coal, may be less than two feet in height. Boys dragging the load seize the roof props first with one hand then with the other while they thrust with their feet against the props behind; the action is that of a swimmer with the body swung clear of the ground, but occasionally the knees strike the floor. Hence on these coalfields the incidence of beat knee is far higher than elsewhere. Beat hand is particularly prevalent in the Cumberland mines, a fact which is ascribed to the hardness of the coal worked; the hands are jarred by the pick handle when the coal is struck. The condition which results is well illustrated. Beat elbow occurs more in Belgium than in Great Britain. On the Belgian coalfield seams are thin and inclined; "much of the travelling at the coal face is done by glissading down on the back, while the elbows are used either as brakes or levers. The likelihood of small injuries being sustained by the points of the elbows is considerable, and almost certainly this is the factor which determines the high incidence of the disease." Radiographs show how in this condition osteophytes detached from the olecranon process come to exist in the chronically inflamed bursa.

---

[1] Report on Miners' "Beat Knee," "Beat Hand," and "Beat Elbow." By E. L. Collis and T. L. Llewellyn. Medical Research Council, Special Report Series No. 39. H.M. Stationery Office. 1924. Pp. 49. 1s. 6*d*.

The clinical and pathological aspects of each condition are well described. In this part of the report allusion is made to the customs and habits of miners. Here reference occurs to the practice of wearing a cord as a garter below the knee.

> "The explanation given of this practice, that by preventing coal and dust getting up the legs, it serves to keep the thighs clean (sic) and so obviates the necessity for washing, is hardly to the credit of the miner. It provides a sidelight on the need for pit-head baths to remove an ingrained habit as well as ingrained dirt. The garter acts in a twofold way: it gives a false security of cleanliness, and acts as a trap for retaining at the knee particles of coal and dirt which get into the trousers. We advise abolition of the order of the garter so that the order of the bath may come into its own. There was for daily use in 1922 in the whole of the kingdom washing accommodation (including three swimming baths) for upwards of 3000 men only, while there were employed underground in that year over 980,000 men!"

The value of protective knee-pads for use is discussed. The authors lay great stress on the need for early and skilled surgical treatment in every case, and particularly for cases of beat hand. "As soon as possible after the acute stage, massage, with passive and later on active movements, must be carried out. This form of treatment frequently accelerates the closure of the wound. It is a mistake to wait until a chronic sinus is closed before beginning massage." Only in this way can be avoided unnecessary risk of complete loss of function of the hand rendering unemployable men in the prime of life. Reference is also made to cases of non-infective tenosynovitis of the wrist; these cases, however, are less numerous and less serious than the cases already mentioned; they result from sudden strain, from unusual exercise of the forearm muscles, or from repeated jarring from using the pick on hard coal or rock. They usually respond quickly to rest.

The authors conclude that (1) the underlying cause for each of the diseases is the same—repeated trauma; and that the first line of prevention is to guard against it, or to minimise the risks so far as is practicable. (2) The determining cause of an acute condition is the ingress of infection to tissues of lowered resisting power; and the second line of defence is avoidance of infection by keeping the skin clean and the general health good. (3) The third line of defence lies in the proper equipment and use of first-aid stations in close touch with skilled surgical advice, which is particularly needed for cases of beat hand. (4) These lines of defence should be strengthened by (*a*) the abolition of garters worn below the knee, (*b*) the use in thin seams of suitable knee-pads, (*c*) attention to smoothness of pick handles. The three diseases are undoubtedly of great importance to the mining fraternity. Since, however, they are seldom fatal, the operating surgeon has been inclined to pass them by and leave them to his house officer. Practitioners who come in touch with the coal-miner will be grateful to the authors for having studied so closely diseases hitherto but little noted by experts.

PERFORATION OF GASTRIC AND DUODENAL ULCERS.

IF a gastric or duodenal ulcer has reached the stage when persistent medical treatment has failed to effect a cure, what are the chances of perforation occurring if operation is not resorted to? This is a question with which most physicians and surgeons are faced more than once, and it is unsatisfactory to note the great differences in the estimates of this risk by various authorities. Thus, Leube puts it at 1 per cent.; Ewald at 1·2 per cent.; Villingk at 2·7 per cent.; Michaux at 3·5 per cent.; Harslof at 10 per cent.; Brinton at 13 per cent.; Nolte at 25·8 per cent.; and Krogius at 30·3 per cent. In a recent publication Dr. O. E. Cederberg[1] has made a study of the cases of gastric and duodenal ulceration coming to operation for perforation at the Wiborg Hospital in Finland in the period 1904–24. In 11 of these cases the operation was performed before 1912, and inadequate records were made on them. In the remaining 60 cases careful records were kept, and it was found that 22·9 per cent. of all the cases of gastric and duodenal ulcer coming to operation were complicated by perforation. Dr. Cederberg, after comparing his own findings with those of other surgeons, concludes that among hospital cases the frequency of perforation is about 10 per cent. With regard to his own material, he notes that only two of the patients were women, and only in ten cases was the perforating ulcer in the duodenum; in the remaining cases the pyloric portion and the minor curvature of the stomach were the sites of the perforation. During the food-restriction period of the war, 1917–1919, the frequency of perforations was almost twice as great as before and after this period, and it would, therefore, seem that war-time rationing played an important part in this matter. In 30 cases the operation consisted simply of closing the perforation and reinforcing the closure with Braun's omento-plasty followed by irrigation and drainage of the abdominal cavity. The mortality was 50 per cent. This poor achievement was largely due to the length of the interval in many cases between perforation and operation, but Dr. Cederberg thinks it was also due, in part, to faulty technique. Since 1914 gastro-enterostomy was often done as an adjunct to closure of the perforation, and of the 34 patients thus treated only six died. The later results, as well as the immediate post-operative results, seemed to be in favour of gastro-enterostomy, for 60 per cent. of the patients thus treated were found at a later date to be in good health, whereas this could be claimed for only 30 per cent. of the patients treated only by closure of the perforation.

THE PREVENTION OF MALARIA.

THE publication of the Parkes Memorial Prize Essay on the Principles of the Prophylaxis of Malaria, by Captain J. S. K. Boyd, R.A.M.C., is completed in the *Journal of the Royal Army Medical Corps* for September. It is a pity that the essay could not have been published in one issue, for such a paper, giving what we may presume to be as complete a statement as the R.A.M.C. can to-day offer, will be widely read and quoted. Captain Boyd lays down four lines of prophylaxis: (1) The reduction or elimination of the reservoir of infection in infected persons; (2) the reduction of the mosquitoes by antilarval measures; (3) the protection of men from mosquitoes; (4) quinine prophylaxis. He advises concentration on one line, carefully choosing the most hopeful of the four, as it is scrupulous attention to detail that brings success. The methods he adopts for each of the four systems of prophylaxis are as follows. For the first system it is essential to keep infected natives at a distance, especially at night, and to give 10 gr. of quinine daily to all malaria carriers, thus reducing their infestation, particularly in regard to gametocytes, and so lessening their chance of infecting mosquitoes. Captain Boyd remarks that some medical officers tempt men to come regularly for their doses by double rations, light duty, or the like. The second system of prophylaxis is good in cantonments, but is almost impracticable on active service. To work on this costly principle demands, as a preliminary, exact and expert investigation on the spot. For example, *Anopheles stephensi*, breeding in wells, is easily mastered, but *A. maculipennis*, breeding in swamps, and *A. maculatus*, in streams, require quite different treatment, so it must be decided what species is to be attacked first. The third system consists in the provision of mosquito nets or repellents; the latter require frequent reapplication, as they are volatile, and are not effective for more than a couple of hours. Fourthly, quinine prophylaxis is carried out by the administration of a dose of 5 or 10 gr. of the drug daily, usually at about 6 P.M. This treatment is of value where mosquitoes are not very numerous, and where administration can be rigidly controlled; but it is not so good on active service unless the mortality from malaria is high. Captain

---

Boyd further indicates certain considerations which must be borne in mind by the War Office when a campaign is projected in malarial districts, if the health and efficiency of the troops is to be kept at a maximum. The War Office should aim, he states, to plan the campaign for the non-malarial season, probably December to May inclusive, and should use, if possible, seasoned troops only, whether native or white. Mosquito nets must be provided, particularly bivouac nets, with a 10 per cent. surplus for each unit for replacement. Malaria diagnosis units, as in Palestine, will be needed, in numbers varying with the extent of the area, not with the number of the troops. On the headquarters staff of the expedition there must be an anti-malarial officer to deal with local problems. Screened huts will be needed for dining and recreation rooms. Base hospitals should be established at the outset, followed as soon as possible by hospital accommodation on the lines of communication. If a native village is heavily infected and near a camp, then the village must be removed. The medical officer of each unit must interest the troops in the prevention of malaria, and see that the scrub round the camp is cut. Care must be taken to keep the mosquito nets in serviceable condition and in nightly use. Further details are given in this very complete and most valuable paper. Captain Boyd's essay is an excellent critical synopsis of much recent work which has been reported in too many periodicals and books to be readily available to officers fighting the disease.

THE QUESTION OF "SLEEP CENTRES."

A RECENT number of the *Medizinische Klinik* (Sept. 21st) contains two articles on the subject of "sleep centres," each of them based on a case in which sleep was a prominent symptom. The paper of Dr. Edwin Hirsch is the more considerable, for it not only discusses the previously reported cases, but reviews the whole question from a general and philosophical aspect. At the time of the influenza epidemic of 1890 Mautner suggested, on account of certain symptoms with which abnormal sleep was associated, that there was a sleep centre in the grey matter of the third ventricle. By a lesion there, he believed, the paths for stimuli from the periphery to the cortex were interrupted and as a result sleep supervened, while cortical impulses were prevented from reaching the periphery and, thus confined, caused dreams. He drew attention to the proximity of the oculo-motor nuclei to this region and associated with it the drooping of the eyelids before and during sleep. Mautner's views were adopted by Economo, Nonne, and others in the earlier investigations into encephalitis lethargica. Trommer, in a monograph on sleep, assigned an active part to the optic thalamus, where he suggested there was a centre for the inhibition of the waking state; with this negative function was combined the control of all those positive acts without which sleep becomes difficult or even impossible. The seeking of a resting-place, the placing of the body in a posture which encouraged sleep, the position of the eyelids and of the eyes in sleep, all corresponded, he urged, with an inhibition of the waking condition, and led up to an assumption of control by the autonomic system so that the pupils became small, the breathing altered, and the distribution of the blood was changed—the whole state of the body indicating at once an entirely changed attitude towards stimuli from the world without. He attached great importance to the change in the position of the eyes. In the waking state they are slightly converged and look slightly down, in sleep they diverge and turn upwards. Freud saw in the sleep position a tendency to return to the posture of the embryo—head bent forward on the chest, arms flexed, legs drawn up. Now, while Mautner's argument may be true that the blocking of the sensory paths produces sleep, it does not follow that the portion of brain, the destruction of which causes the blockage, deserves the name of sleep centre; in fact, it is probably not a centre at all. But if the blockage be brought about by an active switching-off or side-tracking of the sensory impulses by a central mechanism whose peculiar attribute it is to switch them off and on, then the site of that mechanism certainly deserves the title of centre—either sleep centre or waking centre. Is there any indication of the whereabouts of such a centre?

Hirsch's case was one in which an abscess had destroyed the medial part of the left thalamus, and extending posteriorly to the level of the posterior commissure had eroded below the commissure and above the red nucleus, but left both these structures intact. The patient had shown a left hemiplegia, slight right hemiparesis and pyramidal signs on both sides; the pupils were small and equal; the speech had a nasal quality and became slower and more mumbling, like that of a person falling asleep; the legs were rigid in the so-called position of sleep —i.e., partly flexed at hip and knee. General bodily sensation was intact, as also were sight and hearing. The patient slept nearly all the time, but she could be roused by ordinary means. When wakened she opened her eyes, looked round in surprise, and immediately fell asleep again. It was only by constant stimulation that she was kept awake for examination. Two days before death she remained awake for several hours and then fell into a sleep which lasted till her death. The most noteworthy point as regards Mautner's theory is that the sensory paths were anatomically and functionally intact. The abscess extended below the posterior commissure, yet there were no ocular palsies; and Hirsch argues that the region above the oculo-motor nuclei was only affected towards the end of life. In two other cases—viz., those of Adler and Lucksch and of Pette—this same region was also involved, so that there is some ground for locating a sleep centre (or rather a sleeping-and-waking centre) there. The almost constant affection of this area in encephalitis lethargica lends support to this localisation. The question, however, arises whether other parts of the brain may not also possess a controlling power over sleep. Hirsch notes the severe lesion of the left thalamus, both in his own case and in that of Pette. He recalls the connexion of the medial part of the thalamus with the corpus striatum, which probably controls instinctive action, and with the frontal cortex. His argument in this part of the paper is much less rigid than in the earlier portion, but he concludes that the thalamus may initiate the action of the sleep mechanism and (by its connexion with the corpus striatum) cause the instinctive sleep position to be taken up, while by means of its connexion with the frontal lobes it places sleeping and waking to some extent under the control of the will. The thalamus is the centre for the psycho-reflex and sleep is a protective psycho-reflex. We do not only fall asleep when we are exhausted, but in order that we may not become exhausted, and long before exhaustion occurs, we experience a desire for sleep and a weariness that leads to sleep.

These considerations lead the author to postulate at least two sleep centres, one in the left thalamus, the other in the grey matter above the oculo-motor nuclei, and he believes that true sleep can only supervene pathologically when both centres (or one centre and the path connecting it with the other) are put out of action. In connexion with this paper we may recall the upset of the sleeping-and-waking rhythm that occurs both during and after encephalitis lethargica. In the acute stage patients sleep for days with little interruption, and afterwards many of them lose the normal power of going to sleep and perhaps only sleep when exhausted; others are excessively wakeful for part of the acute stage before becoming lethargic. It is the normal alternation that is disturbed. Most of these cases present some oculo-motor palsy, and they therefore lend considerable support to Hirsch's argument for a sleeping-and-waking centre in proximity to the oculo-motor nuclei. The theory that a higher associated centre exists has much in its favour, but in view of our lack of exact knowledge of the functions of the thalamus and corpus striatum, the arguments for its localisation are inadequate.

RECENT ADVANCES IN PHYSICAL CHEMISTRY.

That colloidal behaviour is of paramount importance in physiological problems, and more especially in questions of cellular physiology, cannot be doubted. Unfortunately, the whole subject is surrounded by such a close mathematical veil that it is almost impossible for the ordinary student to approach it intelligently. This has resulted in the development of a special school of "colloidal chemists," and consequently colloids have come to be regarded as substances with a set of laws and properties entirely to themselves. Thus they are said not to obey the ordinary laws of valency in their combinations; they exhibit the peculiar phenomena of adsorption, governed by that equally peculiar equation of Freundlich. The late Dr. Jacques Loeb attacked these views, and attempted to simplify the whole theory of colloidal behaviour. A number of his early papers were collected and published in book form in 1922.[1] Vol. XLVII., 1924, of the Studies from the Rockefeller Institute for Medical Research contains a series of papers in which details of further experiments are given. It will be remembered that Dr. Loeb showed that the irregular combination of proteins with acids and alkalis was not due to any peculiar property of these substances as colloids, but resulted from the fact that no account had been taken of the hydrogen-ion concentration of the medium. He went on to show that proteins could be made to combine with acids and alkalis in strict accordance with the ordinary valency, or stoichiometric laws, provided that the hydrogen-ion concentration of the protein molecule was kept constant. At the same time he emphasised the importance of the isoelectric point of colloids in influencing their behaviour, all the experimental results agreeing with the Donnan membrane equilibrium theory. Dr. Loeb's work on colloidals must be regarded as a great advance, since, like all important researches, it has substituted simple for complex theories. The three papers in the current issue of the Rockefeller Studies are of particular interest since they contain accounts of experiments in support of Loeb's theory.

THE LATE MR. ARTHUR HILL TREVOR.

Arthur Hill Trevor, of the Inner Temple, Barrister-at-law, who died in his sleep after a strenuous day's shooting on the moors round Elvanfoot, Lanarkshire, took so wide and active an interest in the work of the Board of Control, of which he was a Commissioner, and was so unremitting in his efforts to ameliorate the conditions and to advance the treatment of persons suffering from mental illness, that his sudden and altogether unexpected death some weeks ago occasions a public loss and deprives the Commissioners of a colleague of great personality, who was highly esteemed as a friend by each one of them. Born in 1858, the only son of Charles Binney Trevor (an Indian Civil servant), Arthur Trevor was educated at Winchester and at Corpus Christi College, Oxford. He was in those days a well-known cricketer and, indeed, a famous bat. In 1884 he was called to the Bar, and for some years practised on the South-Eastern Circuit and at the Sussex Sessions, and was the author of a book published in 1904 on The Solicitors Act of 1888, with special reference to Procedure and Practice. Appointed Secretary to the Commissioners in Lunacy in November, 1905, he rapidly acquired so close and deep an interest in his new work that it was no small satisfaction to him when two years later he was chosen to fill the vacancy on the Commission created by the death of Mr. G. H. Urmson. Trevor did a prodigious amount of work, not only when on circuit with a medical colleague inspecting institutions and paying other statutory visits to patients, but also in the preparation of reports, memoirs, and other literary work on behalf of the Board. He also accomplished a great deal as a voluntary member of various committees towards a better understanding of mental disorders and the advancement of their treatment; mention, for instance, may be made of the active share he took in the work of the Committee of the Medico-Psychological Association in connexion with Lord Justice Atkin's Committee upon Criminal Responsibility, before which, later on, Trevor, in conjunction with one of his medical colleagues, gave evidence. He also gave evidence before the Royal Commission upon the Care of the Feeble-Minded in 1908; and, upon the passing of the Mental Deficiency Act and the reconstitution in 1913 of the Board of Control, he threw himself heartily into the widened sphere of action of the Commissioners. In 1910 the Medico-Psychological Association, mindful of his active interest in their work and his manifest wish to coöperate more actively than the fulfilment of his official duties perhaps demanded, elected him as an honorary member—a distinction which had only once previously been conferred upon anyone other than a medical man. He was a powerful link between the professions of law and medicine. This was perhaps specially exemplified in him by his constant endeavour to mould administrative action so as to conform, as far as practicable, to medical aspirations. In this connexion his bent of mind, humane and progressive, was conspicuous in his persistent efforts to secure legislation to facilitate the prompt treatment of mental disorder in its incipient and early stages. Up to within a few days of his death he had been preparing with much zest evidence for the Royal Commission on Lunacy Administration and the Early Treatment of Mental Disorder; and at the first meeting of the Commission on Oct. 7th a moving tribute to his memory was paid by the chairman, the Rt. Hon. H. P. Macmillan, K.C.

THE WORK OF BRETONNEAU.

In his presidential address on Bretonneau: His Life and Work, delivered before the Section of the History of Medicine of the Royal Society of Medicine on Oct. 15th, and which was accompanied by an epidiascope demonstration, Dr. J. D. Rolleston said that, with the exception of the chapter on the history of diphtheria in the monograph recently issued by the Medical Research Council, little attention had of late been given in this country to Bretonneau, whose name was chiefly remembered in connexion with diphtheria, without sufficient credit being attached to his other services to medicine. By his clinical perspicacity in conjunction with elaborate post-mortem examinations, Bretonneau had done as much for the study of acute infections as Laënnec had for chronic diseases. Bretonneau was a remarkable personality whose medical achievements could be summarised as follows: (1) He established the specificity of diphtheria and typhoid fever. (2) By his doctrine of specificity he foreshadowed the germ theory of disease. (3) In opposition to the physiological school headed by Broussais, who had discarded the materia medica and reduced treatment to bleeding, leeching, and a starvation diet, he made several valuable contributions to therapeutics. Apart from his being the first to perform a successful tracheotomy for laryngeal diphtheria and to devise a method of administration of quinine which was characterised by Trousseau as a happy combination of the methods of Sydenham and Torti, he resuscitated the use of purgatives in dysentery and of martial preparations in anæmia, and was the first to employ belladonna in constipation and enuresis, and to introduce cod-liver oil into France for the cure of rickets. (4) His work, especially his researches on diphtheria, by which he showed that the Syriac ulcer, malignant angina, and croup were the same disease, illustrated the practical value of the study of the history of medicine.

---

[1] Proteins and the Theory of Colloidal Behaviour. By Jacques Loeb. London and New York: McGraw Hill Book Co.

THE SURGICAL WORK OF ANY YEAR.

ONE of the most wonderful surgical publications in the world, too little known in this country, is a report on general surgery published annually[1] in Berlin. It deals only with the literature of one year, and yet each year we open it with amazement both at the vastness of the field it embraces and at the skill and patience with which the material has been sifted and reduced to order. It consists of a series of brief reports on the surgical work of the year in its various branches, and each report is followed by a full list of all papers published in that branch. The literature of the whole world is included, and the work of British, French, and American surgeons receives adequate attention and quite impartial criticism. The reports consist essentially of short and pithy abstracts of the papers, connected together into a coherent and lucid account. It is therefore possible in a few moments to discover the whole literature on any special point, to gather the leading features of each paper and the general trend of surgical opinion, and to form a shrewd estimate of those papers which are worth consulting directly. Perhaps the best way to give some idea of the nature of the book is to sketch the contents of a small subsection. It appears that in the year 1921 110 papers were published on cerebral tumours, excluding those of the hypophysis. The report deals generally with the statistics of these papers, and then passes on to discuss in detail those relating to gliomata and endotheliomata. Stressing the importance of early diagnosis and of early surgical treatment, it refers to the curious and dangerous fact that salvarsan will often produce temporary relief. X ray methods of diagnosis are briefly outlined, aural symptoms are discussed, and a rapid sketch is given of cases which have been described with tumours showing some peculiar feature. We pass on to the experimental production of tumours and the possibility of their traumatic origin, and the report concludes with a discussion on the technique of removal, the value of decompression, and the possibility of relieving a secondary hydrocephalus. To concentrate such a mass of information into an article of less than six pages, to make that article readable, and to infuse it throughout with a critical appreciation is a very great feat, and those who are acquainted with the prolixity of most German authors would scarcely have expected that it would be accomplished. But to find the same terse completeness all through a volume of a thousand pages is to an Englishman a little disquieting. It reveals an organisation, and a coördination and intensity of effort without parallel in this country. Of the value of the volume to those engaged in progressive surgery there can be no question at all. Indeed, the very existence of such a volume renders a knowledge of German important to any surgeon who would remain abreast of the literature of his subject, and imperative to one who wishes to assist in its advancement. There is, moreover, food for serious thought in the note which appears within the cover by way of preface. It states that at the Kaiser Wilhelms Akademie, Berlin, all the periodicals referred to in the report can be had for the asking by any medical man, student, or apothecary, on payment of an annual registration fee of one mark, to take home if he wishes. It is true that in London the privileged few who can afford it may obtain some such service, and if they can read German they can make use of the Jahresbericht. But we have no service so complete as that to which this report furnishes in Berlin so easy a key.

THE annual dinner of the Royal Society of Medicine will be held at the Hotel Victoria, London, on Wednesday, Nov. 26th, at 7.30 for 8 P.M.

THE quinquennial election of Direct Representatives of the medical profession to the General Medical Council will take place next month, and nominations must be in the hands of the respective registrars by Nov. 6th. Notices of election will be found in the advertisement columns. The present Direct Representatives are as follow, the date, added in parentheses, being that of first appointment. For England: Dr. J. A. Macdonald (1911), Sir T. Jenner Verrall (1912), Dr. R. A. Bolam (1920), and Mr. E. B. Turner (1920). For Scotland: Sir Norman Walker (1907). For Ireland: Dr. Leonard Kidd (1906).

THE jubilee celebrations of the London (R.F.H.) School of Medicine for Women take place this week-end. They include a dinner at the Guildhall, an evening party at the School, and a thanksgiving service at St. Paul's for the increased opportunities afforded to women students of medicine during the last 50 years. Those of the alumnæ of this school who are also past students of St. Mary's Hospital may feel that there is some irony in this thanksgiving at the very moment when St. Mary's Hospital has shut its doors to women after eight years of co-education, during which time well over 200 women students have passed through its school. But the fact that all Scottish, Irish, Welsh, and English schools outside London are open to them, and that in London co-education is available at King's College Hospital, Charing Cross, Westminster, and (for 12 chosen women) at University College Hospital medical schools, shows that while set-backs are to be expected from time to time, the advance of facilities for women's training in medicine has been very great. We congratulate the London (R.F.H.) School of Medicine for Women on its jubilee; it has good reason to be proud of its record.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XCIII.—TREATMENT OF CHOREA.

CHOREA (χορεια, dancing) is a nosological label which has been attached to many clinical manifestations. The Chorea Sancti Viti of Paracelsus, dancing mania or chorea major of subsequent authors, belongs to the hysterical manifestations of disordered motion. The chronic choreas, or symptomatic choreas depending on degenerative changes of the motor cortex and its paths, for example, the syndrome described by Huntington in 1872, are also distinctive. Another group of cases sometimes referred to as "choreiform affections" or "pseudo-choreas," should be called "habit spasm" or "tic." Chorea minor, or Sydenham's chorea, alone is referred to in this article; it is an acute disease of children characterised by irregular purposeless involuntary movements, a varying amount of psychical disturbance, and the frequency with which it is associated with endocarditis and arthritis.

Prevention.

The realisation of the predisposing factors in the life of a girl or boy can do much to ward off an attack of chorea. It is curious how rarely there is a history of chorea in the parents, whilst the protean manifestations of rheumatism are so common. Girls are affected two to three times as frequently as boys, the susceptible age being from 7 to 12 years. The girl in whom the disease is to be anticipated may be tall for her age, thin and anæmic. She is mentally bright, intelligent, and over-conscientious; if at school she may be at the top of her class and facing "special work" for a scholarship. In addition to this mental activity she is emotional and fidgety; in fact, chorea has been cryptically described as exaggerated fidgetiness. Rheumatism in some form is extremely common in the history of these children. The condition of the tonsils therefore requires consideration, for they are often enlarged and unhealthy, and may well be the portal of entry for the rheumatic virus. Fright, worry, and excessive study, though not causes, render the rheumatic child more liable to an attack of chorea; and the avoidance of these factors lies within the field of preventive medicine.

---

[1] Jahresbericht über die gesamte Chirurgie und ihre Grenzgebiete. XXVII. Jahrgang, Bericht über das Jahr 1921. Edited by Dr. Carl Franz, Berlin. Berlin: Julius Springer. 1924. Pp. 996. Price 16.40 dollars.

Early treatment at the onset of symptoms will nearly always cut short an attack, or at least lessen its severity. The earliest symptoms fall into three groups:—

1. *Change of Mentality.*—The child becomes headstrong, resentful of reproof, cries with little provocation, and loses power of concentration.

2. *Movements.*—She is much more fidgety, and is constantly changing position. Her facial muscles show little irregular jerky movements, and her hands are less controlled, as seen by her handwriting.

3. *Muscular Weakness.*—This is always present though commonly overshadowed by the movements.

General Treatment.

There is no specific drug for chorea. The one essential of successful treatment in all cases is rest and quiet, for the movements cease during sleep. This is the opinion of most modern pediatricians, founded on close observation under hospital conditions of children who have been treated as out- and in-patients, with and without medicine. Chorea does not get well by itself, but it is clear that drugs alone will not achieve a cure, for cases drag on month after month as out-patients, rapidly to improve when admitted to hospital, though the same drugs are used. The child must be put to bed and kept there, exception being made only in those few cases where confinement to bed accentuates the nervous disturbances. In this case the child may be allowed up to lie on a sofa. If the movements are at all forcible, bed must be insisted on, care being taken to see that the child cannot injure itself by constant rubbing, for such sores heal tardily. In really violent cases the mattress should be on the floor, and the case constantly watched. No mechanical restraint is ever justified. The question of whether a trained nurse is necessary must be answered in each individual case. The discipline of a sympathetic, but firm, nurse is of great value, and advisable in severe cases where sleep is much disturbed, but milder cases may be better without the introduction of a stranger, provided the mother is sensible.

No special restrictions are called for in the diet, which should be liberal and appetising. Hydrotherapy is a most valuable aid in producing rest and sleep—e.g., shampooing the head twice a day for ten minutes is often successful. Hot or cold packs are excellent therapeutic measures, and are often more effective than soporifics. The hypodermic needle should never be used. When rest and quiet have been assured, two aspects of the disease must receive attention: (*a*) nervous disturbances, and (*b*) rheumatic manifestations.

(*a*) *The nervous disturbances* may call for sedatives, the aim being to produce a certain amount of sleep rather than to abolish the movements. Chloral hydrate gr. vii., trional gr. v., or chloretone gr. v., are the best, and should be given three times a day. (Dosage for a child of 7 years.) Bromides may be usefully combined with the chloral, while chloretone is best given as an emulsion with liquid paraffin or cod-liver oil. These drugs should not be pressed, *for they are not curative*, and if chloretone is employed a watch must be kept for an erythematous rash and incontinence of urine.

(*b*) *Rheumatic manifestations* include pyrexia, a sore-throat, and less often vague pains in the limbs, and call for treatment with salicylates which should be given with alkalis, so long as there is any rise in temperature. I do not think that a prolonged course of salicylates protects the heart, and it certainly has no beneficial effect on the chorea. A sore-throat or even enlarged tonsils should be painted twice a day with—

℞ Salol .. .. gr. xxx.
Glycerini .. .. ʒ ii.
Alcohol 90 per cent. .. .. ad ℥ i.

When the active stage is subsiding, and before the child is allowed up, a short course of arsenic is valuable. It should be given well diluted, in tonic doses only. During convalescence, when the movements have almost ceased, iron should be given in all cases. Cod-liver oil and malt for 2–3 months should be ordered for those who have lost weight. Massage and exercises are beneficial provided they are not started too early. The exercises should stop short of fatigue, and at first should be crude and easy to perform; such as touching the tip of the nose with the finger of an outstretched arm, or pointing the toes while walking along a line or following the pattern of a carpet. Later, games requiring more skilled control may be employed—e.g., building castles with bricks or cards, knitting, exercises on the piano, and so on. Such exercises hasten the recovery of voluntary control of movement.

Treatment of Special Conditions.

Heart.—We have no specific by which to protect the heart from infection, and must trust to early and thorough treatment of the chorea itself to reduce the incidence of cardiac lesions. When there is evidence of the myocardium being affected,—namely, cardiac enlargement, increased pulse-rate, or a diastolic bruit at the apex—we must rely primarily on rest as a therapeutic measure. The rest in bed must be complete, and prolonged until there are no further signs of activity. This may even entail six months' rest.

Chorea Paralytica.—The so-called paralytic cases of chorea are those in which the movements are almost absent, and the muscular weakness so pronounced that the child is virtually paralysed. Such cases call for very careful nursing, and ample light and nourishing diet. Stimulants will be required. Massage must be begun earlier so as to maintain the muscular tone and nutrition pending the return of voluntary movements.

Chorea Insaniens.—In those cases in which the movements are so violent and the mental disturbance so great that the patient is temporarily insane, feeding is difficult. The best forms in which to give nourishment are the semi-solids, such as jellies and custards. Artificial feeding may even be necessary. Sedatives may be pushed. The danger is exhaustion.

Hyperpyrexia, which is rare, and must be treated by salicylates and hydrotherapy.

Chorea Gravidarum.—The usual onset is in the third month of the first pregnancy in very young women. The general treatment of chorea will be successful in the great majority of cases, and only very occasionally will it become necessary to terminate the pregnancy.

After Care.—Whenever possible the patient should be sent into the country or to the sea coast for a prolonged convalescence, since the importance of chorea lies in its cardiac complications.

THE PANEL CONFERENCE:
PREPARING FOR THE ROYAL COMMISSION.

THE annual conference of representatives of local medical and panel committees met at the Central Hall, Westminster, at 10 A.M. on Thursday, Oct. 16th, Dr. H. G. Dain, of Birmingham, presiding for the last time.

Annual Conference Dinner.

Before the formal business was taken it was agreed to appoint at each annual conference a dinner committee formed of the chairman and seven other members in the Home Counties to arrange for the holding of a dinner at the following conference, to which members of the Insurance Acts Committee (hereinafter called simply I.A.C.) amongst others should be invited as guests. At a later stage the seven following names were suggested and approved —viz., Dr. H. S. Beadles (West Ham), Dr. H. J. Cardale (London), Dr. F. Challans (West Ham), Dr. A. P. Eldred (Essex), Dr. J. W. Hill (East Ham), Dr. C. F. J. Scott (Middlesex), and the secretary for the time being of the London Panel Committee.

Personnel of the Royal Commission.

On the motion to receive the report of the Committee for 1923–24, Dr. Brackenbury referred to the negotiations for the 1924 Medical Benefit Regulations, all of which were settled to his satisfaction, except one certification rule. With regard to the Royal Commission to inquire into the working of the national health insurance system, the I.A.C. had asked for a comprehensive inquiry, and the terms of reference had been submitted to the Committee and accepted by them. They could not, however, regard the personnel as satisfactory; they had hoped to have a small, impartial and weighty Commission able to issue a unanimous report, without which the position might be no better in two years' time than it was now. The carefully worded paragraph in the report setting out the I.A.C.'s view is as follows:—

> The Committee did not consider that the personnel of the Commission as a whole fulfilled the requirements, and requested the Minister of Health to receive a small deputation from the Committee to discuss the whole matter. This was agreed to by the Minister of Health, and Drs. Brackenbury, Bolam, and Dain, and the Medical Secretary waited upon him on July 30th. The result of this deputation is considered very unsatisfactory. The Committee has found it necessary to inform the Minister of Health that it is not satisfied with the personnel of the Royal Commission, and is doubtful whether the Commission has that weight which the public might expect in respect to a body which is to report on a matter undoubtedly affecting the future developments not only of the insurance system but of public health in this country. Exception may be specially taken to the presence of Sir Alfred Watson as a member of the Commission. He has been so peculiarly identified with the finances of the Act and his authority has so frequently been involved in acute controversial financial questions that it appears to the Committee that he might more properly have placed his experience and views before the Commission as a witness. However, having made this protest the Committee proposes to place before the Commission its evidence which will be primarily directed to the broad issues comprised in the terms of reference to the Commission.

The Commission had asked for evidence from the I.A.C. as soon as possible, but obviously the memorandum of evidence, Dr. Brackenbury said, must go before the Council of the B.M.A., in so far as it affected other than panel practitioners—e.g., medical officers of health, consultants, pathologists. It was, however, hoped to circulate a draft for the consideration of panel committees in December.

Remuneration.

A motion by Bury, to the effect that the time had now arrived when the panel practitioner should be paid in full for every person on his list, revealed a belief that different parts of the country receive in effect different values for their capitation fee. The Southport representative believed that in his area 8*s.* 2*d.* per head was received instead of 9*s.* 6*d.*, and recently every practitioner had had large numbers taken off his list, many of whom had to be reinstated later. Cambridge believed the capitation fee received in that area to be 9*s.* 11*d.* Dr. Brackenbury, while regarding the central pool as in order, agreed that there might be mistakes in its distribution, although the distribution must necessarily be from the top. There was no longer any unallocated residue, but he thought the time had come when the Ministry of Health might be asked to look back and see how, as a matter of fact, the pool had worked out from year to year, what had been the number of insured persons, and what the amount paid per name on the doctor's list.

Local Health Administration.

A motion by Warwickshire urged the special Committee[1] appointed to prepare evidence for the Royal Commission to take into consideration the possibility of reforming the local organisation of public clinical and preventive medicine, particularly the application of the scheme drawn up by the B.M.A. in 1918 defining the principles governing any steps to coördinate or reconstruct local public health administration. Dr. Brackenbury felt sure the Conference would accept without demur any steps leading to the unification of local health services. It should not be forgotten that there was another Royal Commission sitting, that on Local Government, for more than a year past.

Evidence Before the Royal Commission.

On a motion by Dr. Gordon Ward that the experience and views of insurance practitioners were of such paramount importance as to demand separate and authoritative presentation to the Royal Commission, Dr. Brackenbury pointed out that in regard to general matters it would be the endeavour of the Evidence Committee to express the opinion of the medical profession as a whole, and in what he might call intra-insurance matters to be guided by the opinion of panel committees. The evidence to be tendered would be of very wide scope.

Inequality of Benefit.

A motion by Kent to remove at the earliest possible moment from approved societies the administration of sickness benefit gave rise to an interesting discussion. Inequality of benefit offered by various societies is admittedly leading to some hostility towards the panel practitioner and militates against the success of the insurance scheme. Dr. Brackenbury suggested a clear separation of medical benefit and cash benefits so that the medical insurance service could get on with its own job of medical benefit in the widest sense. Cash benefits might then be left in the hands of the voluntary agency, the two being connected inherently by the system of certification. Dr. Beadles set out his well-known views on the desirability of entrusting medical (including additional) benefit to a local health committee, funds being equalised in a central pool, deposit contributors who are at present not insured getting their proper share. The present system is eminently unsatisfactory, in which the sum paid out as a maintenance wage varies according to whether it is called sickness, unemployment, accident, or old age benefit. Amalgamation of the whole of State insurance (medical benefit excepted) would, he is satisfied, rid the system of the Poor-law stigma.

---

[1] The personnel of this Committee is as follows:—
Ex-officio: Mr. J. Basil Hall, M.C.Camb. (Bradford), Dr. H. B. Brackenbury (Hornsey), Dr. R. A. Bolam, LL.D. (Newcastle-upon-Tyne), and Mr. N. Bishop Harman (London).
Appointed by B.M.A. Council: Dr. J. H. Badcock, L.D.S. (London), Prof. H. R. Dean, F.R.C.S. (Cambridge), Lt.-Col. F. E. Fremantle, M.P., O.B.E., M.Ch., F.R.C.P. (Hatfield), Prof. A. J. Hall, M.D., F.R.C.P. (Sheffield), Mr. Somerville Hastings, M.P., M.S., F.R.C.S. (London), Dr. R. Wallace Henry (Leicester), Sir Thomas Horder, Bart., M.D., F.R.C.P. (London), Dr. W. J. Howarth, C.B.E. (London), Sir Ewen J. Maclean, M.D., F.R.C.P. (Cardiff), Mr. E. W. G. Masterman, F.R.C.S. (London), Dr. John Stevens (Edinburgh), Mr. E. B. Turner, F.R.C.S. (London), Sir Cuthbert S. Wallace, K.C.M.G., C.B., F.R.C.S. (London), Mr. H. J. Waring, C.B.E., M.S., F.R.C.S. (London), and Dr. Mabel Ramsay (Plymouth) (nominated by the Medical Women's Federation).
Appointed by Insurance Acts Committee: Dr. H. G. Dain (Birmingham), Dr. E. R. Fothergill (Hove), Dr. H. J. Cardale (London), Dr. J. G. McCutcheon (Glasgow), Dr. J. P. Williams-Freeman (Andover), Dr. R. W. Craig (Dalkeith), Dr. H. S. Beadles (Romford), Dr. J. W. Bone (Luton), Dr. T. Wood Locket (Westbury, Wilts), Dr. P. Macdonald (York), Mr. H. S. Souttar, C.B.E., F.R.C.S. (London), and one other (to be appointed to the vacancy caused by Dr. Brackenbury now being an *ex-officio* member).

Fees for Anæsthetics.

The report of the I.A.C. lays down what the Committee considers to be the circumstances under which, in accordance with resolutions of the Conference, a fee may be claimed from the local practitioners' fund in respect of an anæsthetic administered to one of his insured patients. Dundee proposed an amendment to extend the scope of the statement to include circumstances under which the fee was chargeable to the patient, and it was referred to the I.A.C. to prepare and circulate a clear statement of wider scope. East Sussex desired to limit the occasions on which a fee should be payable out of the practitioners' fund to the administration of an anæsthetic for an operation by a panel practitioner within the terms of his contract. The Conference evidently preferred local option. On an appeal from Northumberland to consider the difficulties of practitioners in small towns with local hospitals, the question was raised, and answered in the affirmative, whether the Distribution Committee on which Dr. Dain had a seat could consider the loading of local pools according to the amount of anæsthetics given.

National Insurance Defence Trust.

On the report of the trustees Dr. Brackenbury answered the doubt expressed in some quarters that with the capitation settlement and the appointment of a Royal Commission there was no longer any need for such a fund. Possibly not, he said, for many years, "but we never knew." A large sum of money behind them was always a help to negotiators. Dr. A. Cox reported that amounts to a total of £1991 had been received since the report (showing £66,000 odd) was made up to August 31st, 1924. Criticism was directed against the loan to a panel committee at a low rate of interest for the establishment of a public medical service. It was, however, pointed out that this item came well within the objects for which the fund was instituted. Members of the Conference were in favour of an ultimate widening of the scope of the trust fund to cover the whole expense of the I.A.C. and of the annual panel conferences.

The Thousand-Pound Fine.

In regard to the case of two panel practitioners in Lancashire charged with making improper charges to insured persons for medicines supplied, who were fined £1000 by the Ministry of Health, the report contained the considered opinion of the I.A.C. that the penalty was out of all proportion to the offence for the following reasons :—

(1) That after much investigation, in addition to some few cash cases, there were only 13 cases of charges being made amounting to just over £60 spread over a period of six years ;

(2) that the investigation was only made possible by the coöperation of the two practitioners themselves in placing their books at the inspection of the Insurance Committee ;

(3) that the practitioners did not make direct suggestion of a charge except in three cases ;

(4) that no further accounts were rendered by the doctors after they were warned ;

(5) that the sums received from patients had been refunded ;

(6) that the action of the doctors was rather in ignorance of the law than with intent to evade the obligation with a view to private profit ; and

(7) that the doctors concerned enjoyed a reputation for good work and character.

A motion was brought at the Conference by Manchester to the effect that the vindictive action of the Ministry in this case disclosed a position of such danger to panel practice that in the event of a repetition of such action the I.A.C. be instructed to take immediate steps for notices of resignation to be sent in by all panel practitioners. The story of the case was brought up to date by the reading to the Conference of two letters which had since passed between the secretary of the B.M.A. and the Ministry. Dr. H. F. Oldham (chairman, loc. med. comm., Lancs) queried whether such a fine could properly be regarded in the nature of a penalty at all. A fine of £250 would have met the case and acted as a deterrent. Such a large sum, he felt, would not have been awarded by a court of law, and awakened a feeling of distrust of the Ministry to the detriment of the service. It was, he agreed, clearly necessary in such a case for the penalty substantially to exceed the profit made. Manchester and Salford, by their representatives, supported the validity of the position that the medicine prescribed by a panel doctor is more valuable to the patient than the medicine in which he has no confidence. Another representative countered with the remark that the mental suggestion of doctors' physic was in the mind of the Ministry of Health in inflicting a severe fine, the Ministry desiring to impress the real facts of the case on the practitioners of Lancashire. It was further pointed out that the offence was committed by a practitioner of little experience, who was told that charging for medicines supplied was customary and who after being informed to the contrary only gave out medicine in two cases in the district, one private in nature, the other a dying man. Dr. A. E. Larking instanced a similar case which had occurred in Bucks, where a fine of £5, considered sufficient by the Insurance Committee, had been increased by the Ministry to £100. Dr. Oldham reiterated, in defence of the Lancashire panel, that they were all anxious to carry out strictly the wording of regulations ; there was no such feeling as had been attributed to them. In the case under discussion, the habit of paying for medicines had grown up in the practice, and after 1921 there was only evidence to show that the regulations had been broken in about three cases. The doctors had never tried to induce patients to take their physic ; the patients persisted in paying. The serious points in the case were that the Insurance Committee, acting under instruction from the Ministry, had spent 47 days in house-to-house canvassing and in getting bills produced, and when Bury could no longer afford the expense the Lancashire committee took on the inquiry. This inquiry practically exonerated the doctors of evil intent and there remained only mistakes which justified no such excessive or even vindictive penalty. The practitioners had, in effect, been deprived of a whole year's remuneration. The Ministry surely had no right to dictate to an insurance company what its action should be. After prolonged discussion two resolutions proposed by Dr. Brackenbury and seconded by Dr. Oldham, as follows, were put to the meeting and carried with acclamation :—

1. That the Conference has heard with very great regret the letter from the Ministry, dated Oct. 14th, and is of opinion that the fine inflicted in the case referred to is greatly excessive, taking into consideration all the circumstances disclosed in the report of the Inquiry Committee and that it is contrary to the principles of English justice to assume offences over and above those proved at the inquiry and to inflict any penalty in regard to such unproved offences.

2. That the Conference further protests against the procedure of the Minister in this case in so far as the Ministry which itself had to pronounce judgment, directly invited the Lancashire Insurance Committee to revise the con

clusions which that Committee had reached after inquiry in accordance with the regulations.

Automatic Transfer.

On a motion by Ayrshire, now that unlimited choice is allowed to panel patients, to revert to the system of automatic transfer, it was learned that the I.A.C. had already asked the Ministry to make this change, for which its clerks were pressing, on the ground of economy of time.

Public Medical Service for Dependents.

Devonshire desired to ask the I.A.C to obtain the opinion of panel practitioners generally in regard to support being given to public medical service schemes on the lines of the model scheme drawn up by the B.M.A. The motion was withdrawn in order to leave entire liberty to each insurance area to act as it thought best.

Retirement of Chairman.

At the close of the formal business Dr. P. Macdonald rose to propose a vote of thanks to Dr. Dain, who after five years' service was retiring from the charmanship of the annual conference. Always a good chairman, Dr. Dain had, he said, become first-rate, with a rare combination of good temper, tact, and ability. In reply Dr. Dain expressed his gratitude to the Conference for having given him the opportunity of perfecting himself in the art of chairmanship. Dr. J. W. Bone and Dr. Brackenbury were also accorded warm thanks. Dr. E. K. Le Fleming (Dorset) was elected chairman of the Conference for the coming year.

The Conference closed at 5.45 P.M.

PRESENTATION TO DR. BRACKENBURY.

A RECEPTION was held at the King Edward VII. Rooms, Hotel Victoria, London, on Wednesday evening, Oct. 15th, for the purpose of making a presentation to Dr. H. B. Brackenbury. There was a large gathering of medical men and women whose work had brought them into contact with Dr. Brackenbury, especially in the sphere of medical insurance practice. The guests were received by Dr. H. G. Dain and Mr. H. S. Souttar, respectively chairman and hon. treasurer of the Testimonial Fund. After a delightful preliminary entertainment of music and dancing, the formal presentation took place.

Sir Humphry Rolleston spoke for the medical profession as a whole. He said: This is a great, if not unique, occasion—a spontaneous, splendid tribute by members of the medical profession, usually individual and somewhat inclined from their circumstances to plough a lonely furrow, to one who for years has rendered them great services without fear and without any thought of reward. The immense success and popularity of this testimonial express the profession's keen sense of gratitude to Dr. Brackenbury for his wise leadership, his constant guidance of the difficult work of the Insurance Acts Committee, and his skilful advocacy of the claims—monetary and of other kinds—of the insurance practitioners during the last eight years; especially before the Ministry of Health, at the Board of Arbitration as to the capitation fee in 1920, and the Board of Inquiry in January of this year. His conduct of affairs on the last occasion was such a triumph that it drew from all, even his official opponents, open admiration for his broad knowledge, ability, and dignity. It must not be forgotten that this success was but the culmination of many years' laborious training in public affairs, and unselfish work on behalf of the British Medical Association, which has already shown its appreciation of these services by conferring on him its blue ribbon —the gold medal of the Association—at the Bradford meeting. It is pleasant to know that there are such men amongst us, and surely we honour ourselves by acclaiming Brackenbury a high-minded gentleman of great moral courage, a medical statesman of exceptional ability, the friend and benefactor of the medical profession.

Dr. Dain said: During the passing of a generation there had been a change in the relation of medical practitioners to the public and to one another. A generation ago they started professional life as individualists, going out into the world in solitary fashion. The patient only saw his doctor when his disease was already a serious thing. All that was changed. A tremendous decrease in the death-rate had gone hand in hand with an increase in the doctor's work. He was now called in for small ailments; a sense of responsibility had developed among the public for the illness of the individual, in origin no doubt due to a desire for protection against infectious disease. The medical profession was now asked for its collective opinion on matters of public importance and for concerted measures of treatment. Doctors met and talked things over. In this change Dr. Brackenbury had played a leading part. We were there to honour him as one of the greatest leaders the medical profession had ever produced. With unique experience of public affairs as educationist, alderman, and ex-mayor of his borough, he combined a grasp of detail, a remarkable memory, an enviable capacity of sizing up a new problem and of seeing in a flash the implications which it involved. He hoped that as a Member of Parliament we might soon have his services in the House of Commons. He concluded by asking Dr. Brackenbury to accept what was offered as an expression of gratitude and goodwill.

Dr. Dain then handed to Dr. Brackenbury a cheque for £6500 and a handsome canteen of silver inscribed "To Dr. Brackenbury as a mark of the respect and esteem in which he is held by fellow members of the medical profession."

Dr. Brackenbury said that criticism and opposition were natural to the earlier part of any public man's life, and it was with something of astonishment that he was emerging from the sombre chrysalis stage into one of appreciation and encouragement. With that feeling of astonishment there came to him an overwhelming sense of the extraordinary kindness of it all. It was true that he had spent a good deal of time, and had made financial sacrifices, in trying to help the medical profession on certain lines. But a good many other people had been doing exactly the same thing. To him it had all been very interesting and very enjoyable. He could not recall a happier three-quarters of an hour in his life than when making a certain speech before the Court of Inquiry. There seemed to him to be no reason why one particular individual of a group—a group who had been doing work in common, who had influenced one another and guided one another, and as a group had done far better than any individual could have done by himself—should be chosen for a presentation. He recalled a sentence of Francis Bacon's, "I hold every man a debtor to his profession, from the which as men of course seek to receive countenance and profit, so ought they of duty to endeavour themselves by way of amendment to be a help and ornament to their undertaking." It was a maxim which perhaps some of them did not think about as often as they might. For himself, he had never professed to be an ornament, even in the Baconian sense of the word, but he had quite honestly tried to be a help to the profession, and it appeared from what was being done to-night that in some sense and in some degree he had succeeded. "I want to thank you most heartily," Dr. Brackenbury concluded, "for these beautiful things, and for this wallet containing such an embarrassing number of delightful possibilities. But more than that, believe me, I thank you for the sincerity and the kindness and the encouraging appreciation which I am sure have been in your hearts and minds in making this presentation."

Mr. Souttar proposed the thanks of the meeting to Sir Humphry Rolleston, and the rest of the evening was spent in renewing social ties and in anticipation of the Panel Conference on the following day.

RAINFALL AND HEALTH.

A STUDY OF RECENT METEOROLOGICAL DATA.

(BY A SPECIAL CORRESPONDENT.)

IT was as recently as 1921 that we were close to a water-famine of disastrous intensity.[1] In the south-east of England it seemed as if a pall, pervious to sunshine, but impervious to wet, had spread over the land. Rain-bearing winds favoured the north and west. Even experts took it for granted that the rainfall could not fall below 60 per cent. of the average, and yet in not a few places the rainfall, to use an Americanism, was cut in half. Truly, 1921 was a remarkable year. Yuccas flowered as if England were their real home. Time-worn expressions such as "weather permitting" lost their significance. Rivers, ponds, and ditches dried up, flowers languished and died, fields looked like patches of desert, children's playgrounds blew away in dust. Clouds came and went, the barometer rose and fell, winds seemingly favourable for rain proved fickle, the law of averages flouted the pundits. The happy army of outdoor-lovers came into their kingdom, and fortunately, those who prophesied disease were confounded—we are speaking here in general terms without necessarily disputing the judgment of those who contend that the drought was responsible for local troubles. There were, however, graver aspects: agricultural and horticultural losses and perils to men and beasts. As regards water-supply, the Ministry of Health showed itself alive to the potential danger of the situation, and at an early stage formed what might be described as an unofficial expert committee, composed largely of non-Ministry officials who placed their services unreservedly at the disposal of the health service.

The Book of Normals.

The recent summer has blotted out the memory of fine weather and adds gusto to a study of a fascinating pamphlet[2] recently issued by the Meteorological Office, which gives the monthly normals of rainfall (1881-1915) for nearly 600 stations, along with the height above sea-level and the latitude and longitude. At the end of the report there is an alphabetical index with page references, which will enable the prospective holiday-maker to plan a 1925 holiday in areas which are relatively dry without being low-lying or swept by bitter winds. Seathwaite (at an elevation of 422 feet) has an annual rainfall of 129·48 inches in startling contrast to Shoeburyness (elevation 13 feet) with 18·87 inches. Regarding London the index is dumb, but the information sought will be found under Camden-square (24·47 inches), Greenwich (23·50 inches), and so forth. Many people think, not without reason, that mountains mean heavy rainfall. In the whole of Scotland there are few spots so beautiful as Glenquoich (elevation 569 feet) with a rainfall of 110·75 inches. Yet at Grantown-on-Spey (elevation 700 feet) rainfall is nearly four times less (31·15 inches), although the elevation is greater and the scenery at least as beautiful.

Wet and Dry Months.

Table I. is interesting as showing the general rainfall averages (in inches) month by month computed from isohyetal maps, from which emerge the following facts:—

Taking the British Isles as criterion figure (41·41), England (32·67) stands easily first in point of dryness, and Scotland (50·32) and Wales (50·14) are about equally bad from a wet point of view. April is pre-eminently the driest month, and October or December the wettest. Speaking of the British Isles as a whole, January, February, and March (10·26), and July, August, and September (10·22) might be described as average months, October, November, and December (13·16) as wet, and April, May, and June (7·77) as dry months.

TABLE I.—*General Rainfall Averages in Inches.*

—	Worst month.	Best month.	Year.
England	October, 3·69	April, 1·98	32·67
Wales	December, 6·00	May, 2·95	50·14
Scotland	December, 5·88	June, 2·83	50·32

The London Balance-Sheet.

Table II. shows for London (Camden-square) the normal rainfall and the rainfall for the calendar years, 1921, 1922, 1923, and the first nine months of the present year.

TABLE II.—*Rainfall in Inches, Camden-square, London.*

Month.	1881–1915	1921	1922	1923	1924
January ..	1·86	2·48	2·81	1·28	2·75
February ..	1·67	0·18	2·20	3·04	0·65
March	1·83	1·19	1·51	2·39	0·73
April	1·54	1·29	3·02	1·37	3·14
May	1·76	1·03	0·83	2·28	3·14
June	2·02	0·37	1·12	0·42	2·47
July	2·38	0·13	3·85	3·24	5·69
August . ..	2·21	1·65	2·54	2·01	2·72
September ..	1·82	2·50	2·13	1·29	2·59
October. ..	2·63	0·63	1·02	5·94	—
November ..	2·36	2·01	1·43	1·46	—
December ..	2·39	1·13	3·14	2·31	—
Year	24·47	14·59	25·60	27·03	23·88 for 9 months.

At the end of 1921 the deficiency in the rainfall was 9·88 inches. The rainfall for 1922 was 25·60, an excess only of 1·13, reducing the 1921 deficiency to 8·75 inches. In 1923 the rainfall was 27·03, an excess of 2·56, bringing the 1922 deficiency to 6·19 inches. The 1924 rainfall is 23·88 for the first nine months, and if we assume *normal* rainfall for the last three it will amount to 31·26, an excess of 6·79 inches which would wipe out the deficiency and leave 0·60 inch to the good. For the 24 hours ended 9 A.M. Oct. 1st, 1924, 0·44 inch of rain fell, but this is included in the September total. Up to 9 A.M. Oct. 9th, an additional 1·05 inches have fallen (Camden-square). In many parts of the country, however, much heavier falls have been recorded.

Notable Records.

Not much can be said against 1922, or even 1923, as regards the rainfall, but certainly the last six months of 1924 have been depressing. During these months, when genial sunshine and fine weather are generally expected, the rainfall has amounted to 19·75 instead of a normal of 11·73 inches. A number of incidents of meteorological importance have occurred during the years under consideration. In January, 1910, Paris suffered from serious and alarming floods. At the close of 1923 and the beginning of 1924 a similar visitation was experienced, and for a time the position was fraught with grave anxiety. April, 1924, was a most inclement month, excepting the Easter week-end, which was gloriously fine. On May 1st London was bathed in a fog and the Rivers Thames and Lee were in flood. July hit Hampstead very hard. 7·6 inches of rain fell during the month, the largest recorded fall in any month since observations began there in 1858. There was a terrific thunderstorm in the London area on July 22nd, and at the climax of the storm at Hampstead 0·36 inch fell in two and a half minutes. The rainfall at Cannington, near Bridgwater, Somerset, for the 24 hours ended 9 A.M.

---

[2] Air Ministry. The Book of Normals of Meteorological Elements for the British Isles for Periods ending 1915. Section V.: Monthly Normals of Rainfall. H.M. Stationery Office. 1924. Price 4s.

on August 19th, was 9·04 inches, a record which has only once been surpassed (9·56 inches at Bruton, Somerset, on June 28th, 1917). Other phenomenal falls of rain within 24 hours have been 8·20 inches on Oct. 11th, 1916, at Loch Quoich (Inverness), and 8·03 inches on Nov. 12th, 1897, at Seathwaite (Cumberland). On July 9–10th, 1923, a terrific thunderstorm broke over London. In six hours there were 6924 flashes of lightning, an average of 19 per minute, and 2·10 inches of rain fell at Camden-square. In 1914 a waterspout produced the most disastrous results near Carr Bridge (Inverness), and on July 8th, 1923, the same locality suffered again in much the same way.

Weather Psychology.

There can be no question of the influence of weather on health. There are the now familiar object-lessons of Alton and Hayling Island, and the rays of the sun are being used more and more each year to ameliorate pathological conditions and to prevent the occurrence of disease. The effect of exposure to strong prevalent rain-bearing winds on early cases of phthisis has again been emphasised recently.[3] At the same time, we must preserve a sense of proportion, and remember that one of the charms of our climate is its variability. Ever since the glorious year of 1921, the man in the street is convinced that the weather has been disastrously wet. It may be that the psychology of the nation has been changed as a result of the war. The late Sir William Osler, among his many charming attributes, refused to allow the weather to ruffle his feelings. He saw beauties in Nature at all seasons; snow, sleet, and rain were to him but variations of an admirable whole. We think the absence of sunshine, the usual corollary of wet weather, has a depressing and therefore a bad influence on our lives, but where in the past we used to complain of the weather with a latent smile, we complain now with a scowl. Summation of such stimuli may drive us into the hands of the alienist, and that is happening to some of us in regard to the weather. The "grouse" becomes a sort of "hymn of hate" which grows in intensity each time it is sung. Curse the weather a little more vehemently each time and you become a "weather hog." The sooner we all cultivate the Mark Tapley spirit, the sooner shall we reach the serenity of past years.

THE LONDON MEDICAL EXHIBITION.

A REVIEW OF THE EXHIBITS.

(Concluded from p. 781.)

The London Medical Exhibition closed after a successful session on Friday, Oct. 10th. In a previous issue we dealt with the large display of Drugs and Foods *; this week we notice the principal Surgical Apparatus and Instruments, Milk and its Preparations, Spas and Waters, Medical Books, and other things of medical interest which do not fit in to any general classification.

Surgical Apparatus and Instruments.

On entering the upper hall of the exhibition one of the first objects to attract attention was the "Westminster-Eidinow" Sun Ray Arc Lamp for Actino-Therapy which is equally efficient on alternating or direct current (Agents: Allen and Hanburys Ltd.). It has a powerful long flame rich in ultra-violet rays, the proportion of which can be increased or lessened by the use of varying electrodes. The National Institute for Medical Research recently called attention to the value of arc-light baths (The Lancet, 1924, i., 1290), and we understand that the lamp has been ordered by 16 large hospitals or sanatoriums.—X Rays, Ltd., incorporating F. R. Butt and Co. (11, Torrington-place, Gower-street, W.C.), attracted a large number of visitors by reason of their display of apparatus of practical utility, all of which were of British manufacture. Chief place must be given to an ingenious tube stand specially designed to carry the additional weight of protection called for in the latest N.P.L. specification, without sacrificing any of the advantages of lighter tube stands. It allows of all necessary movements above and below the couch, and the detachable end box can be rotated in any direction by means of easy-working universal joints. Another piece of apparatus of merit was the new model combined couch and screening stand, while the thermotank—practically an electrically-heated water-bath—for developing films at a constant temperature evoked much commendation.—The General Radiological and Surgical Apparatus Co., Ltd., incorporating M. Schaerer, S.A. (204–206, Great Portland-street, W.), in addition to high-pressure sterilisers, baby incubators, hospital furniture, and surgical instruments showed the Dental Heliodor, a complete self-contained X ray unit, the Neo-Thermoflux, a diathermy apparatus embodying the latest improvements, and the original Hanau Quartz (ultra-violet) and radiant heat lamps.—The exhibit of films by Kodak, Ltd. (Kingsway, W.C.), also attracted much attention. On the wall were displayed some beautiful 14 × 17 negatives and enlarged dental prints of quarter-plate size. The improvement in the "Dupli-Tized" X ray film negative due to the use of the Potter-Bucky diaphragm was clearly shown, and the large number of photographic X ray accessories made this exhibit a most interesting one.

The stall of Down Bros., Ltd. (21 and 23, St. Thomas's-street, S.E.), afforded an opportunity to the medical practitioner to select those instruments or appliances which might be particularly adapted to his or her requirements, for here, among a general collection of surgical apparatus, were many new instruments recently introduced, and modifications of existing patterns carried out at the suggestion of surgeons. Many of this firm's instruments are made in stainless steel. Notable features of this exhibit were the "Up-to-Date" Operation Table with oil pressure pump for raising and lowering and with other controls which can be easily operated by the anæsthetist; and a portable apparatus for tracheal insufflation anæsthesia. —Mayer and Phelps ("Chiron House," 59–61, New Cavendish-street, W. 1). Here also a good selection of instruments could be made, including the "Chiron" Dissecting Forceps, designed to give delicacy of control and not to tire the surgeon's hand, the Gillies' Suture Forceps and Scissors combined, and a new syringe for local anæsthesia. Though only shown by a photograph particular attention was drawn to the "Empire Operation Table."[1]—The Surgical Manufacturing Co., Ltd. (83 and 85, Mortimer-street, W.), in addition to the "Barton" Sphygmomanometer, of which they made a special feature, exhibited a large assortment of surgical instruments and hospital and consulting-room appliances. The "Barton" electric Auroscope and the "Servic" high-pressure Steriliser were examined with great interest by many visitors.—Many ingenious contrivances were shown by the "Aurorascope Co.," Ltd. (18–19, Fulwood House, Fulwood-place, High Holborn, W.C.), for use by the aural or ophthalmic surgeon and by the general practitioner. Much interest was shown in the Standard Morton Ophthalmoscope convertible and re-convertible at will into the electric Fundus Aurorascope and in the Pocket Urinary Outfit containing reagents with which anyone can test at the bedside in a few minutes.—Surgical dressings, ligatures, and dental requisites were shown by Fassett and Johnson (Seabury and Johnson Preparations, 86, Clerkenwell-road, E.C.), particularly noticeable being "Meads" Rubber Adhesive Plaster, "Gold Cross" Absorbent Cotton, Wintergreen Plasters, and a boil plaster of red lead, camphor, and olive oil on a base of boric lint.—Various appliances for defects of the feet were exhibited by the Scholl Manufacturing Co., Ltd. (1–4, Giltspur-street, E.C. 1), and H. E. Curtis and Son, Ltd. (7, Mandeville-place, W.), had an excellent selection of abdominal supports and belts, trusses, elastic hosiery, and so forth. Colonial Liquid Paraffin of extra high viscosity for use as an intestinal lubricant was also shown by this firm in tasteless and flavoured forms.—Domen Belts Co., Ltd. (456, Strand, Charing Cross, W.C.), showed a large selection of belts based on physiological and anatomical considerations for use in pregnancy, accouchement, umbilical hernia, and floating kidney. Particularly noticeable was a hypogastric and gastroptosis belt for employment in cases of extreme corpulency and of pendulous abdomen. By the use of a peculiarly constructed flexible steel spring with a well-cushioned pad an equitable and gentle pressure is maintained immediately above the pubes.—A big display of microscopes for biological, histological, and research purposes, as well as for microphotography, attracted a constant crowd of visitors at the stand of Chas. Hearson and Co. (68,

* In this report Saccharomycin, a well-known product of the British Organotherapy Co., Ltd., was inadvertently attributed to Messrs. Allen and Hanburys, Ltd.

[1] The Lancet, 1924, ii., 51.

Willow-walk, Bermondsey, S.E.), where there was a fine collection of biological and other apparatus used in research work. In particular, good pattern microtomes, freezing and recording apparatus were exhibited. The frequent microscopical demonstrations were much appreciated. A new and extensive catalogue of the physiological, pathological, botanical, and similar apparatus made by this firm is in the press.—"Tycos" Sphygmomanometers, portable and surgical types, were shown by SHORT AND MASON, LTD. (Aneroid Works, Walthamstow, E.), one of their chief features being that there is no glass tube to break. The surgery type has a 6-inch dial and the size enables more accurate observations than are possible with a smaller type. It is designed to be used on the table or fastened to the wall.—The display of clinical thermometers by G. H. ZEAL, LTD. (75–77, St. John-street, E.C., and 29, St. John's-lane, E.C.), attracted attention by reason of some ingenious contrivances for resetting the instruments. The "Repello" is an ordinary clinical thermometer with a flattened bulb of flexible glass, this on being pressed between the finger and thumb forces a column of quicksilver down the bore, which on coming in contact with the buffer of gas between the two columns forces the registering column back below the divisions. The "Acello" is a pocket thermometer in which the centrifugal principle is used to reset the instrument.

Among appliances for the deaf particular interest was shown in the stand of GENERAL ACOUSTIC CO. (Acousticon House, 18, Hanover-street, W.), where there were shown electrical and non-electrical aids for the deaf in large variety. One of the latest introductions of this firm is a microphone made in tortoise-shell, weighing 1½ oz. only, which can be worn under the tie or within a lady's dress without inconvenience. The receiver is equally light. A form suitable for medical men, in which the telephone earpiece with a push button for conveniently and quickly turning the current on and off, can be carried in the waistcoat pocket and instantly attached to a very light head band when required for use. Other notable exhibits were a wireless box 'phone for the deaf, acousticons concealed in dainty vanity bags for ladies' use, church sets consisting of a microphone for use near to the preacher while the receiving apparatus is distributed among the deaf in the congregation, and a judge's acousticon for use on the bench.—At the stand of the DEAF APPLIANCE CO., LTD. (58–60, Wigmore-street, W. 1), many electrical and non-electrical instruments for the deaf were shown, among which was the Micromega, a small receiver which fits easily into the ear and does not require to be held. This instrument is recommended in suitable cases for nerve deafness or slight middle-ear deafness. The Earlux is made in different types for portable or table use.—At the stand of "ARDENTE ACOUSTIQUE" (95, Wigmore-street, W.), who make some 30 different types of their apparatus to relieve definite and specific conditions of deafness, attention was drawn to the "Ardenta Acoustique" Stethoscope specially designed for doctors suffering from deafness, and the "Ardente Acoustique" church installation which makes it possible for deaf people to join in the service from any part of the building.

Much interest was shown in the British Benedict Metabolism Apparatus, HERBERT E. KENDRICK (3, Morley-avenue, Highams Park, E.), an apparatus designed to meet the needs of physicians who require a portable outfit for use in hospital, consulting-room, or patient's home. The basal metabolic rate is determined at the bedside by measuring the amount of oxygen consumed during a known period. Comparison with a chart showing average normal consumptions, followed by a simple calculation, gives the plus or minus metabolic rate. Results are obtained without analysis, and no breathing bag, meter, or electric current is required. The instrument can also be used as a vital capacity spirometer, or for the administration of medicinal oxygen.

Milk and Milk Foods.

The stands exhibiting milk and milk foods included GLAXO (56, Osnaburgh-street, N.W.), whose interesting display of their products—Glaxo Standardised Full Cream, Three-Quarter and Half Dried Milk, Prescription Glaxo (Humanised), Glax-Ovo,[2] and Ostelin—were a centre of inquiry. Ostelin is a new product consisting of an anti-rachitic extract of cod-liver oil diluted with glycerine so that three drops of the glycerine suspension are equivalent to a teaspoonful of cod-liver oil.—HORLICK'S MALTED MILK CO. (Slough, Bucks) showed their well-known preparations the vitamin content of which was pointed out to visitors. The various preparations of this company form easily digested and highly nutritious diet for invalids, convalescents, and infants.—The WEST SURREY CENTRAL DAIRY CO., LTD. (Cow and Gate House, Guildford, Surrey), demonstrated their methods of preparing dried milk. The raw milk is supplied by prize Dorset and Somerset herds.—TRUFOOD, LTD. (The Creameries, Wrenbury, Cheshire, and Lever House, Blackfriars, E.C.), showed Humanised Trufood, Trufood Full Cream, and Secway (Sweet Whey Powder); while at the stand of THEW, HOOKER AND GILBEY, LTD. (Buckingham), Hooker's Malted Milk, a food beverage prepared from pure fresh cream milk combined with extractives of selected cereals was exhibited. The analysis shows moisture, 1·50 per cent.; mineral salts, 3·50 per cent.; maltose and lactose, 55·80 per cent.; dextrine, 16·00 per cent.; protein, 14·00 per cent.; and fat, 9·20 per cent.

Spas and Waters.

BATH, famous from Roman times to the present day, which, if for that reason alone, can claim to be the premier spa of the Empire, was well represented by an attractive exhibit of books and pictures. The latest addition to this bathing establishment is a Zander institute for medico-mechanical treatment.—BUXTON, with its chalybeate waters, is another place known to the Romans, where in Tudor times Mary Queen of Scots, suffering from rheumatism, visited for relief. This watering place was also well represented by descriptive literature and pictures.—DROITWICH, England's brine baths spa, drew attention to its facilities for treating rheumatism, gout, neuritis, and certain forms of heart and nervous disorders, among other ailments.—At HARROGATE two new departments have been installed, one for nose and throat treatment, and the other for the mountain sun treatment, with the mercury vapour lamp. A pamphlet giving a summary of the Harrogate waters and treatment has been compiled by the Harrogate Medical Society and can be obtained from the Corporation Wells and Baths Department. Similar literature, it may be mentioned, can be obtained from the other English spas mentioned, as well as from TORQUAY, described as England's premier marine spa, where special treatments are Torbay seaweed baths, Dartmoor peat baths and packs, and Pistany radio-active mud baths and pack, while there are other treatments numbering nearly 40.

The attractive exhibit of INGRAM AND ROYLE, LTD. (Bangor Wharf, 45, Belvedere-road, S.E.), abundantly proved that the scarcity of Carlsbad water, the result of war conditions, no longer exists in this country. Its Czecho-Slovakian origin is emphasised by the labels on the bottles. Bottled waters in great variety were shown by this firm, who are exporters of natural mineral waters, salts, and pastilles. The French natural mineral water Vichy Célestins had a prominent place in the exhibit.

Medical Books.

Medical books were shown by BAILLIÈRE, TINDALL AND COX (Henrietta-street, Covent Garden, London, W.C.); WILLIAM HEINEMANN (MEDICAL BOOKS), LTD. (20, Bedford-street, London, W.C.), who also exhibited specimen tubes of pure glycerinated calf lymph; H. K. LEWIS AND CO. (140, Gower-street, London, W.C.); and by STANLEY PHILLIPS, (48, Brondesbury-road, London, N.W.).

Miscellaneous.

CADBURY BROS., LTD. (Cocoa and Chocolate Manufacturers, Bournville, Birmingham), exhibited their specialty and showed an interesting collection of the raw material in its different forms.—The JAEGER CO., LTD. (95, Milton-street, E.C.), demonstrated the health-conducing properties of their pure wool fabric, and called attention to a specially woven double material holding a layer of air between its inner surfaces.—The exhibit of the GAS LIGHT AND COKE CO. (Horseferry-road, Westminster, S.W.) demonstrated economical and effective solutions of the smoke problem.

CLERICAL, MEDICAL, AND GENERAL LIFE ASSURANCE SOCIETY.—The centenary year of this society is being celebrated under good auspices, for the report, which was presented at the hundredth annual general meeting on Oct. 10th at the society's offices, 15, St. James's-square, London, S.W., was satisfactory both in regard to business and financial progress during the year which ended June 30th, 1924. The new assurances numbered 1518 for the total sum of £1,617,691, and the net new life business was £1,324,691, as compared with £1,210,064 in the previous year. The total premium income showed the large increase of £41,184, and reached £609,492. The net rate of interest earned after deduction of income tax was £4 13*s.* 2*d.* per cent. The claims by death amounted to £348,737. As the result of the year's transactions the Life Assurance Fund showed an increase of £467,267, and now amounts to £7,961,035.

---

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Meat Poisoning in Germany.

THE Health Office has published a report dealing with meat poisoning in Germany during the year 1923. According to the report 61 epidemics of meat poisoning occurred with a total of 3090 cases, of which 20 were fatal. In 59 per cent. poisoning followed upon the consumption of minced meat, and in 4 cases frozen meat had been consumed. Bacteriological investigation revealed paratyphus bacilli in 29 cases, *Bacillus enteritidis* Gaertner in two, *Bacillus enteritidis* Breslau in one, *Bacillus botulinus* in two, *Bacterium proteus* in three, *Bacterium coli* in two, and putrefactive bacilli in three. In three instances no micro-organisms could be detected, and in the remainder no bacteriological investigation was carried out. The month of August had a record of 14 epidemics, the remaining 47 being spread over the other months.

The Journal of the German Medical Women's Association.

The German medical women have formed an association of their own. This association has begun to publish a new quarterly journal as its official organ, under the editorship of Dr. Heusler-Edenhuizen and of Dr. Laura Turnau, who had both represented Germany at the recent International Congress of Medical Women in London. The aims of the association are described in the first number as follows: To promote the union of the medical women of Germany, to discuss questions of social hygiene from the standpoint of the medical women, to care for invalid medical women who are unable to work, and to give advice to younger medical women and women medical students. The association will be a branch of the International Medical Women's Association. The first issue contains an introductory letter of Dr. Francisca Tiburtius, the oldest medical woman in Germany, and Prof. Lydia Rabinowitsch-Kempner contributes an article on the work of the medical women in the fight against tuberculosis.

Sixth Congress of the German Society for Urology.

This Congress was held in Berlin from Oct. 1st to 4th, and was opened by Prof. Karl Posner (Berlin), who read a paper on the medico-social significance of urology. It was, he suggested, preferable to consider many of the symptoms arising from disease of the urogenital system as indications of some constitutional weakness—such symptoms, for example, as enuresis, bladder weakness in women, and albuminuria. The results obtained by Rosenstein by means of pneumo-cystography were worthy of particular note. In this procedure the pre-vesical space and then the bladder itself was filled with oxygen. This procedure was indicated where there were strictures in the urethra, and was useful in showing up tumours in the region of the bladder. Dr. Blum (Vienna) gave a report of clinical observations of normal and pathological ureters. Reflux of urine from the bladder into the ureter occurred in three types of condition: (1) where the urinary apparatus was normal and there was a strong pressure in the bladder as occurred in hypertrophy of the prostate; (2) in diseased conditions of the openings of the ureter—e.g., wounds from ureteral calculi and in spinal affection, such as tabes; and (3) where there was anti-peristalsis in the ureter caused by mechanical or thermal stimuli. An explanation was thus offered for many cases of ascending infection. Reflux of urine also occurred where there was a certain rigidity of the ureter, and, further, where one kidney was damaged so that the urine from the other kidney ascended the ureter of the damaged kidney and caused infection. Added to these was the condition of congenital permanent reflux in the ureter known as "megalo-ureter." Prof. B. Bloch (Zürich) considered that palpation of the ureter per vaginam was an important diagnostic aid. If only one ureter could be palpated it could be regarded as pathological, especially if tuberculosis were suspected. According to Stöckel, every palpable ureter was a pathological one. Prof. H. Kümmel (Hamburg) spoke of the surgical treatment of nephritis. He said that the operation of decapsulation had only slowly come into its own, and its successes were on the increase. This operation was first performed (through a mistaken diagnosis) by Harrison, who was later followed by Israel in Berlin, Rovsing in Copenhagen, and Edebohl in the United States. He said that it was not likely that a new collateral circulation was established when the kidney was decapsulated. The action of the nervous system on the decapsulated kidney was important. A great number of sympathetic twigs were found connected with the renal artery. His own experience with the section of the sympathetic nerves of the organ, which had lately been attempted, showed that a considerably improved blood-supply of the kidney was obtained. Indications for surgical interference were (1) nephritis after acute infectious disease, of vital importance if anuria were present; (2) toxic nephritis, including eclampsia; and (3) acute infectious nephritis in its various degrees. Renal calculi often gave the indication for decapsulation. Prof. F. Volhart (Halle) opposed the views of Prof. Kümmel, and questioned whether surgical interference in nephritis was justifiable.

Infectious Diseases.

Infectious diseases have shown a considerable decrease in 1923. Diphtheria has decreased by 6000 and scarlet fever by 5000 cases, puerperal fever from 6422 to 5592, trachoma from 1522 to 1192, trichinosis from 110 to 25 cases. On the other hand, typhoid fever has increased from 10,992 to 13,162 cases, and hydrophobia from 52 to 65 cases. Encephalitis lethargica was notified in 271 cases, this being the first time that the notification of this disease was compulsory. As to small-pox, a report of the Health Office of the period from 1919 to 1921 states that 5021 cases of the disease occurred in 1919, an extremely large figure compared with the former state of things; in 1920 and 1921 the number fell again to 2115 and 689 cases respectively. The case-mortality fluctuated between 14·1 and 16·7 per cent. The cause of the great number of cases in 1919 was that during the revolutionary troubles of that year many unvaccinated foreigners from abroad entered Germany without permission, and that the control of vaccination had been much relaxed. The mortality among the unvaccinated or people vaccinated a long time ago has been greater than among the recently vaccinated.

The German Red Cross.

The German Red Cross, which was formerly to a great extent an auxiliary force of the Army Medical Corps, has now entered on a new sphere of activity. It assists the Government in the care of invalids, in the prophylaxis and treatment of epidemics, and in the care for the general health. For that purpose it continues to train nurses, professional as well as voluntary (the latter doing service only in cases of epidemics and urgent occasions), male attendants, laboratory assistants, and disinfectors. It also maintains depots of sanitary appliances and of dressing materials, and arranges for popular lectures on hygiene. 390 hospitals and convalescent homes and 500 creches are connected with the Red Cross or managed directly by its local branches. 12,000 parish nurses work in 1294 parishes among the indigent classes. The women's organisation of the Red Cross has 2000 branches with 800,000 members. The badge of the Red Cross is, according to the law, a privilege of the Red Cross Association. Only societies belonging to or connected with that organisation may use the badge. The badge was formerly granted by the war office, but now that under the Versailles treaty the Red Cross is independent of the Army Medical Department, it is awarded by the Ministry for Home Affairs.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the statistics of four counties and three combined county areas for 1923 :—

Name of area.	Estimated (R.G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Hertfordshire.	337,800	17·2	9·6	0·7	1·4	1·6	25	42	2·9
Cumberland ..	219,720	21·1	12·7	1·0	1·2	1·9	34	74	5·6

Hertfordshire.

Dr. H. Hyslop Thomson states that in more than 30 per cent. of the cases of pulmonary tuberculosis visited the patient occupied a bedroom with two or more other persons. This, he says, indicates the existence of overcrowding and the urgent need for additional houses. The County Council have prepared a scheme for promoting the welfare of blind persons which came into operation on April 1st, 1923, and is in addition to the provisions made by the education authority. In carrying out the scheme, the County Council have secured the coöperation of the County Nursing Association and the Hertfordshire Association for the Blind. The register of blind persons in the county contained at the end of the year 304 names, 137 being males and 167 females. The work of ascertaining and dealing with mental defectives has been continued during the year. Ninety-eight mental defectives were reported to the medical officer, 54 being males and 44 females. Of the 98 cases, 9 were defective and epileptic, 4 were epileptic, and 22 either dull and backward or suffering from some form of physical defect associated with backwardness. The absence of adequate accommodation in certified institutions, more especially for low-grade and complicated cases, is seriously felt from time to time. In the maternity and child welfare work the voluntary centres are linked up to the Council scheme with excellent results. There is a decided increase in the number of children and mothers who have had dental treatment. Ten nurse-midwives were trained at the Watford Training Home during 1923, and the County Council grant of £500 has been given to the County Nursing Association. 2685 confinements were attended by midwives alone. There are 147 midwives practising in the county, 142 trained and 5 untrained. The midwives paid 10,680 antenatal visits, and six maternal deaths occurred among their cases. Dr. Thomson reports that the regulations suggested by the Ministry of Health have lessened the nuisance caused by the dumping of outside refuse in the county. A further improvement has resulted from the action of the Ministry in securing the covering of railway wagons which convey rubbish into the county. Improved arrangements for the removal of refuse in the county itself are needed.

Cumberland.

Dr. F. H. Morison reports that there is great difficulty in getting patients to accept sanatorium treatment for tuberculosis at a time when the treatment would be most hopeful. The supply of milk to expectant and nursing mothers and young children has had to be continued on a fairly large scale owing to unemployment in the west of the county. Dr. Morison draws attention to the wide powers granted by the Maternity and Child Welfare Act of 1918, and expresses his regret that neither the medical nor the nursing staff is adequate to carry out anything like a complete scheme. Dr. Mark S. Fraser submits the report of the Englethwaite Industrial Colony, in which he points out that industries are necessary in the treatment of pulmonary tuberculosis, that they are more valuable as part of the treatment than as a preparation for new occupations, and that only under exceptional circumstances can they be self-supporting. Nevertheless, the after-care report shows that of 34 men who are working and earning a living, 15 are working at trades learned in the colony, 6 at their former employment, and 13 at other occupations.

Cambridgeshire.

Dr. Frank Robinson states that there are now only three untrained registered midwives practising in the county as compared with 44 when the Midwives Act of 1902 first came into operation. Through the County Nursing Association the area of the county unserved by nurses is gradually being reduced. Since the war ten new associations have been assisted to start work in 20 rural parishes. The proportion of midwives' confinement cases in which medical aid has been summoned has increased from 5·2 in 1919 and 7·1 in 1922, to 9·1 in 1923. The visiting of expectant and nursing mothers and children under school age by the staff of the nursing associations shows a considerable increase. This work is important in rural areas where a welfare centre is not a practical proposition. The visits to expectant mothers have been useful in securing special medical assistance when necessary at Addenbrooke's Hospital, and also in securing dental treatment. The County Council have no maternity and child welfare centres under their direct management, but make grants in aid to centres carried on by voluntary agencies in rural parishes. Home helps provided by the County Nursing Association are also subsidised, but there is difficulty in getting suitable women to undertake this work. Six additional open-air shelters with bedding outfit have been purchased, bringing the total provision up to 135. Since the receipt of the Ministry's circular on after-care a provisional sum has been included in the estimates, and it has been decided to confer with the After-care Association as to the best way of complying with the suggestions of the Ministry. Most of the male consumptives who receive institutional treatment are provided for at Papworth. Dr. Robinson compares the economic value of providing treatment for lung consumptives and bone and joint cases respectively, and emphasises the loss to the community caused by permanent crippling in the latter cases. The report on the Sale of Food and Drugs Acts reveals the usual inadequate penalties for adulterating milk. In two cases where there was 10 per cent. of added water, the penalties were 10*s.* with 15*s.* costs and £1 with 10*s.* 6*d.* costs respectively. The annual reports of the district medical officers of health refer to the impossibility of dealing with houses which are overcrowded or unfit for habitation. In the Newmarket rural district cottages with three bedrooms are badly wanted. The Chesterton council are endeavouring by means of the subsidy and the proceeds of a penny rate to build cottages to be let at a rent that the labourers can pay, but are finding it a difficult task. Comparing the Census results of 1911 and 1921, all the districts in the administrative county, with the exception of the borough of Cambridge and the rural district of Chesterton, show a decreased population.

County of Fife.

Dr. G. Pratt Yule's report deals with the conditions of the districts Cupar, Dunfermline, Kirkcaldy, and St. Andrews, which make up the landward area of the county. The regulations for the notification of chicken-pox terminated at the close of the year. During the last two years the cost of drugs prescribed for the treatment of tuberculosis has been defrayed by the county. The number of prescriptions issued by a small minority of practitioners (about 1 in 10) suggests to Dr. Yule that prescribing with them is a routine habit intended as a placebo for the patient. The tuberculosis officer, Dr. G. M. McGillivray, emphasises the value of the health visitors in improving the environment of the consumptives. He also states that there is a tendency to notify cases at an earlier stage, and that quite a large number of practitioners now notify "suspects." The improvement in home conditions after return from a sanatorium is evidence of the great value of the sanatorium as an educator. Dr. W. P. S. Johnson, the V.D. medical officer, shows that the dispensary opened in Dunfermline in November, 1922, has been very successful in attracting patients both male and female and in securing their continued attendance. During the year only 10·2 per cent. of the cases ceased to attend before completing their course of treatment, and Dr. Johnson thinks this favourable result is due to the method adopted of scrutinising the case cards monthly and writing under confidential cover to the defaulters. Every endeavour is made to treat the source of infection in the case of congenital disease, and in some such cases whole families have been examined. Towards the end of the year a number of boroughs were invited to grant facilities for lectures to men and to women on the evils of venereal diseases, but the majority appeared to be averse to such teaching. Under maternity and child welfare work, Dr. Yule says there are eight nurses working whole-time in the capacity of health visitor, tuberculosis nurse, and assistant inspector of midwives within the districts Dunfermline, Kirkcaldy, and St. Andrews and the ten boroughs therein, but that this service does not exist in the Cupar district. There are no centres, and Dr. Yule thinks that centres have unsatisfactory features apart from the fact that they do not attract the mothers whom it is most desirable to reach. Two midwives were reported to the Board; one of them was put on probation, the other was the only midwife in a wide and sparsely populated district, and in these circumstances no action was taken. The facts of two cases where unqualified women were in attendance at confinements were reported to the Procurator-Fiscal, who held that the provisions of the Act on emergencies covered one case, and the words "under the direction of a registered medical practitioner" the other, so no action was taken. No application has yet been received to sell a designated milk within the county area. Dr. Yule does not think it is feasible to enforce the meat inspection regulations of 1923 in scattered county districts with private slaughter-houses situated frequently many miles apart.

Herefordshire.

Dr. Herbert Jones points out that it is a constant practice to complete the building of a cottage before ascertaining whether there is any suitable water-supply available. About one-fourth of the cottage houses are supplied from distant sources, and the task of achieving a proper standard of cleanliness is thus made difficult. No site, he says, should be considered suitable for building if there is not a supply of water on it. There is much negligence in all parts of the district with regard to the protection of dip wells. As a rule there is no difficulty in making these wells safe by enclosing them and providing an outlet by a pipe to slightly lower ground. The slop-drains from far too many cottages discharge into the nearest roadside ditch, and even in the case of newly erected houses this practice has been permitted. Dr. Jones has no sympathy with occupiers who complain that their pail closets are offensive or a nuisance. The remedy is in their own hands, as pail closets can be readily used as earth closets. There were 27 new houses erected during the year. In many parishes more houses are required. The regular inspection of houses has been in abeyance owing to the high cost of repairs. Dr. Jones thinks it should now be resumed. The rural housing problem is not an easy one to solve. Dr. Jones thinks the State might give assistance by providing expert engineering advice for the provision of rural water-supplies and sewage disposal works. He believes that a great deal can be done to reduce cost by mass production and scientific organisation. Subsidies or grants from the State, he says, will never reduce the cost of building; on the contrary, they have always sent it up. From 10,000 to 12,000 men, women, and children come into the combined district for about four weeks in August and September as hop-pickers. All sorts of out-buildings are used for their accommodation, though on an increasing number of farms there are specially erected buildings. Bye-laws with respect to the accommodation of hop-pickers have been adopted with great advantage by the Hereford, Leominster, and Weobley districts, but the Bromyard and Ledbury councils have not yet come into line. Dr. Jones reports that in the various districts little attention is given to cleanliness in the matter of milk production.

West Gloucestershire.

Surgeon-Captain O. W. Andrews reports that there was a considerable number of cases of small-pox during 1923. The bulk of the cases were in the East Dean district. Of 188 cases notified, 161 were unvaccinated, 17 had not been vaccinated since infancy, 9 were vaccinated after contact, and 1 was said to have been vaccinated while a prisoner of war in Germany. There were no deaths. The mildness of the epidemic led many to think that it was not really small-pox, but Dr. Andrews has no doubt on the subject. The spots were more spherical than those of chicken-pox, and the distribution was quite different. In the cases of small-pox the spots were on the face, back, wrists, forearms, ankles, and legs, and very few on the chest or abdomen. In the chicken-pox cases the trunk was chiefly affected. Experience showed that if vaccination was carried out within the first three days of the incubation period, the symptoms of small-pox seldom developed. In cases vaccinated on and after the fifth day the vaccination was successful, the vaccinia and small-pox ran concurrently, and the severity of the small-pox appeared to be decreased. A considerable amount of vaccination was done in the affected schools, and Dr. Andrews estimates that half the children of school age are now vaccinated and that if to these be added the number of the recent sufferers from the disease some protection against epidemics should be afforded for some years. Forty-seven cases of typhoid and paratyphoid fever were notified. Careful inquiries were made as to possible food sources of the epidemic in which the Ministry of Health and the medical officer of health for the city of Gloucester (Dr. Ronald Berry) took part. No definite conclusion was reached, but the Ministry of Health discovered that in several outbreaks occurring in widely separated districts there was one article of food common to all those who had been attacked—viz., currants. It is suggested that currants are not always carefully washed, and that the protection afforded by the material in which they are embedded prevents them being sterilised during the cooking process.

South-West Kent.

Dr. S. Nicol Galbraith only began his duties on Sept. 1st, 1923, in succession to Dr. J. S. Tew, whose death occurred on Sept. 27th, 1922. Dr. Galbraith reports that the hop-picking season of 1923 passed without any serious outbreak of infectious disease. During this time the population becomes practically doubled, especially in the rural districts of Tonbridge and Maidstone. In Tonbridge rural district the normal population of 17,000 was increased to about 37,000. Before the arrival of the pickers the huts are thoroughly inspected and the water-supply and sanitary accommodation are seen to. The inspectors report that the accommodation for pickers is much improved during recent years. Good use has been made by the farmers of army huts and bell tents. The pickers bring their own sheets, blankets, and domestic utensils, while the farmers provide cooking sheds with benches and fuel. Most of the camps have company's water. Dr. Galbraith found one camp much overcrowded, and the people standing in a queue waiting for water from the one tap, which was situated in a quagmire. In some instances the scavenging and cleansing of the camps could be much improved. It is suggested that the camps might be run more on military lines, and that young farmers with army experience could readily introduce simple methods of camp sanitation and detail a few of the pickers to clean up and keep the camps in order. One farmer complains of the lack of supervision of the food sold by hawkers to pickers. Voluntary nursing and first aid is carried out by charitable organisations in several of the villages and this meets a great need among the pickers. Minor ailments such as scalds and burns are frequent among the children. "Much credit," says Dr. Galbraith, "is due to the doctors in the hop-picking areas on whom a great deal of work is thrown."

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 11TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 55; scarlet fever, 2278; diphtheria, 1115; enteric fever, 150; pneumonia, 673; puerperal fever, 53; cerebro-spinal fever, 3; acute poliomyelitis, 35; acute polio-encephalitis, 3; encephalitis lethargica, 41; continued fever, 40; dysentery, 7; ophthalmia neonatorum, 128. No cases of cholera, plague, or typhus fever were notified during the week. The cases of continued fever were notified from Bethnal Green, the number there given is 10, the larger number mentioned in the total apparently being a misprint.

Deaths.—In the aggregate of great towns, including London, there were 9 deaths from enteric fever, none from small-pox, 10 from scarlet fever, 17 from diphtheria, 11 from measles, 21 from influenza. In London itself the diphtheria deaths numbered only 5, the deaths from infantile diarrhœa 28.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. R. M. Richards is placed on the Retd. List with the rank of Surg. Capt.

D. Duncan to be Surg.

J. G. Holmes to be Surg.-Lt.

ROYAL ARMY MEDICAL COLLEGE.

Capt. J. S. K. Boyd to be Asst. Professor.

ROYAL ARMY MEDICAL CORPS.

Maj. R. L. V. Foster to be Lt.-Col., vice Lt.-Col. E. E Parkes to half pay.

TERRITORIAL FORCE.

Capt. V. Townrow resigns his commn. and retains the rank of Capt.

ROYAL AIR FORCE.

The undermentioned are granted permanent commissions in the ranks stated: Flight Lt. T. McClurkin and Flving Officer C. V. D. Rose.

Flying Officer (hon. Flight Lt.) G. R. Hall is promoted to the rank of Flight Lt.

INDIAN MEDICAL SERVICE.

Lieut.-Col. J. H. Murray, C.I.E., acting superintendent of the Yeravda Central Prison, has been appointed Acting Inspector-General of Prisons. Major E. E. Doyle, acting superintendent of the Ahmedabad Central Prison, succeeds Col. Murray as Superintendent of the Yeravda Central Prison. Lieut.-Col. G. McPherson, C.I.E., has been granted a further extension of leave for six months. Major A. N. Thomas has been permitted to return to duty.

Capts. R. R. M. Porter, J. R. D. Webb, and A. C. Macrae to be Majs.

Monawar Khan Afridi to be temp. Lt.

Capts. Narendra Nath Ray (who retains the ranks of Capt.) and Gokal Chand Batra relinquish their temporary commissions.

The King has given to Lt.-Col. B. Biggar, R.A.M.C., His Majesty's Royal licence and authority to wear the Insignia of the Third Class of the Order of the Nile, which has been conferred upon him by the King of Egypt in recognition of valuable services rendered while employed with the Egyptian Army.

DEATHS IN THE SERVICES.

Surgeon-General Richard Henry Quill, C.B., A.M.S. (retd.), who died on Oct. 18th at Cheltenham at the age of 76, entered the army as assistant surgeon in 1872. He served in Afghanistan in 1879–80, and afterwards became senior medical officer of the Thames District. He later held a similar post in the Ceylon Command, and was then appointed to the administrative medical charge and P.M.O. at Netley. He retired in 1908 and received the C.B. in 1917. He leaves a widow and one son.

Medicine and the Law.

A Muddled Bequest.

THE late Mr. Robert Newton appears to have made his own will, or at any rate whoever did so failed to check accurately his property and his language in disposing of it before he died. Consequently his estate has been impoverished by the necessity to take out a summons in the Chancery Division, the arguments on which required the presence of counsel representing (1) the executors, (2) the Attorney-General, (3) the treasurer of the Imperial Cancer Research Fund and others, (4) St. Dunstan's Hostel and the Salvation Army, and (5) the Royal Free Hospital. The will gave a bequest to "The Society for Cancer Research," and no such body exists. It also gave to St. Dunstan's Hostel "My 50 ordinary shares in Mexican Eagle Oil Company," whereas at the time of the making of the will and of his death the deceased owned bearer certificates of 150 fully paid ordinary shares in the Mexican Eagle Oil Company. The residue of the estate of the deceased was left on trust for the St. Dunstan's Hostel, the Salvation Army shelters, London, and the Royal Free Hospital. Mr. Justice P. O. Lawrence made an order that by the "Society for Cancer Research," the testator meant the Imperial Cancer Research Fund. This, it will be noted, was in accordance with the doctrine by which on such occasions a *cy-pres* interpretation—i.e., one "as near as possible"—is taken to express the wishes of the testator. The legacy to St. Dunstan's Hostel, his lordship held, applied to the 50 shares in the Mexican Eagle Oil Company, and did not include the 150 shares. It was ordered that the costs of all parties as between solicitor and client should be paid out of the residue. How much of the estate would be left for distribution by this was not stated, but it is evident that the testator largely contributed to the defeat of his own benevolent intentions.

Inquest at a Mental Institution.

At the County Mental Institution, Devizes, an inquest was held recently on the body of Mrs. S. Salisbury, the wife of a gardener at Corsham, Wilts. The case had excited interest locally on account of efforts made by the husband of the deceased to obtain the discharge of his wife in order that she might be at home (or in the Chippenham Poor-law Institution), and on account of complaints made by him that he had not been sufficiently informed as to an accidental fall which his wife had had, resulting in injury to the upper end of the femur, as shown by post-mortem examination. The X ray examination of this had given the impression that there had been an impacted fracture, but the mental condition of the patient had prevented the obtaining of a satisfactory photographic print. A letter to the husband had informed him of the fall, but had not mentioned that a fracture had been sustained or was suspected. There was, however, in addition, a division of medical opinion at the inquest as to the necessity for retaining the deceased in the institution, and Dr. A. E. Peake, vho had endeavoured on behalf of the husband to btain her discharge, was of opinion that she might ave been allowed to return home. In the end the ury found that death was due to "disease of the rain and lowness of her general health as from the octor's evidence," and added that "everything ossible was done for the deceased by the authorities." he inquest appears to have developed, owing to the ircumstances referred to, into something like an nquiry into the policy and conduct of the asylum uthorities and the Board of Control in retaining Irs. Salisbury at Devizes, and the fact that more efinite information had not been given to the husband s to the injuries she had sustained was evidently artly the cause of this, and was to be regretted. he accident, however, was proved by the evidence o have had nothing to do with the death, and bviously the fall described, which might have taken lace at any time and in any place, was much more romptly and efficiently dealt with in the institution han it could have been in the home of the deceased.

Rent of a Lock-up Surgery.

Numerous decisions have made it clear that remises which are used partly for business, trade, r professional purposes and partly as a dwelling-ouse, are regarded as a dwelling-house under the ent Restriction Acts, if they were originally let at ast partly as a dwelling. It is, however, also established that premises originally let for business purposes nly and afterwards used either wholly or partly as a welling-house are not entitled to the protection fforded by the Acts. A correspondent consults us s to whether the rent of a lock-up surgery is restricted nder the existing Acts. No doubt this depends rgely upon the purpose for which the house was let o him. If, as is probably the case, it was let to him ith the intention that the ground floor should be sed as a lock-up surgery and the remainder as a welling-house, the whole of the premises could roperly be regarded as a dwelling-house under the ent Restriction Acts, for in that case the house ould have been "let as a dwelling." On the other and, in the case of McDougall *v.* Bell, heard on pril 8th of this year, the facts were that a doctor ad leased premises comprising four rooms, the lease roviding that they were to be used for no other usiness purpose than that of a medical practitioner. he doctor used two of the rooms for professional urposes and the remaining two were occupied by a oliceman and his wife, who acted as the doctor's aretaker and help. It was held that this was not a welling-house as the people who occupied the house welt there as the servants of the doctor who used the remises only for his business purposes. In this case, hich is one of the latest on the point, Mr. Justice cton said that the real main and substantial purposes f the user of the premises was a question of fact. egarding the increased rent which is being asked om our correspondent, it is, of course, legitimate for e landlord, where a tenant sublets part of a house, increase the rent payable by the tenant by an mount equivalent to 5 per cent. of the net rent of e part sublet, and in that case the tenant can increase e subtenant's rent by 10 per cent. of the net rent f the part sublet.

Medical Inspectors in Nullity Suits.

The President of the Divorce Court recently nnounced in court that the medical inspectors ppointed for the purpose of nullity suits had resolved give their services gratuitously in the cases of poor ersons. This action on their part places them on e same footing on such occasions as the barristers nd solicitors who appear for poor persons. Sir enry Duke referred to the sacrifice of emoluments tailed by a "self-denying resolution," upon which ose concerned are to be congratulated. The relief fforded by the Divorce Court thus becomes increasgly less a monopoly of the classes that are comparavely "well-to-do," through the combined action of embers of the professions of law and medicine.

Correspondence.

"Audi alteram partem."

INTRA-OCULAR TENSION IN MYOPIA.

To the Editor of THE LANCET.

SIR,—In my Arris and Gale lecture three years ago (THE LANCET, 1921, i., 469) I set out my conviction that I had discovered the cause of myopia—namely, that it was produced by dilatation of the eye through increased intra-ocular tension caused by back pressure through the veins of the eye. Further observation has led to unexpected results. Not only does the myopia remain stationary on the advice given below, but it may diminish, and in some cases the eyes may even become emmetropic. The patient should be told to avoid any exercise which causes the veins of the neck to stand out, as, for instance, lifting a heavy weight in a stooping position, moving up and down on the hands or the use of dumb-bells, and not to bend over a book in reading or writing. There is no need to restrict the reading so long as this is done with comfort. The eye evidently possesses a power of contracting under diminished intra-ocular tension; to what extent this may occur is a matter for investigation. My object in writing this letter is to bring these facts to the notice of those who have to examine the eyes of school-children. I am, Sir, yours faithfully,

F. W. EDRIDGE-GREEN.

London, S.W., Oct. 9th, 1924.

DENTAL DRESSERS.

To the Editor of THE LANCET.

SIR,—There is always a danger of a discussion on principles and important subjects trailing off into trivialities, and Mr. Pitts's letter would have the effect of helping to side-track a great forward advance in social care. I had already noted the effect of Circular 1279 as a hold-up in the school dental service for the forthcoming number of the *Journal of School Hygiene*, and therefore now only refer to some points of objection.

Mr. Pitts shifts the ground when he apologetically says the real issue is not the efficiency of the dental dressers. The whole case stands or falls on the shorter training, providing persons who can give hygienic instructions and do minor work more cheaply and for practical school purposes just as well as if they had had years of wide-range training. This has been shown for public health purposes by Fones, the originator of the dental hygienist movement, and borne out by its success in America, New Zealand, and where tried in this country, so that it may be taken to be a possibility which experience has placed above mere theoretical discussions.

Again, Mr. Pitts's experience with the recently qualified dentists is against all we have heard for years. My own impression for the past 20 years was that there was a general shortage for the whole country, and it is only in terms of the whole country that it can be discussed. I am not alone. In the report of Sir George Newman, where he discusses the situation rising out of the report of the Dental Committee, he says: "The first fact of the situation is therefore a shortage of dentists" (Report, 1920, p. 97). "There are fewer dentists now in proportion to the whole population than there were 40 years ago, but there is a considerably greater need now than then." The Dentists Act Committee were of the opinion: "The number of registered dentists entering the profession is only likely to suffice for the service of the rich and comparatively well-to-do." These opinions probably deprive the theory of a plethora of dentists, of its value as a reason for holding up a great forward health movement.

For the qualified dentist, Mr. Pitts tells us the "examinations are not easy, and cover a wide field," but we do not need a steam-hammer to crack nuts, and it is not likely that public authorities will pay for all this luxury training that is unrequired. They cannot afford to pay for ten dentists with a five years' training, when for all practical school purpose nine dental hygienists, each with a 12 months' training, and a superintending dentist to whom they can refer cases, will completely cover the field at a much smaller cost.

The immense value of school dentistry was first officially put forward in this country in the Report: "There is no way of dealing with money in the interests of public health which will return so enormous a gain to the population for the small expense required as this matter of school dentistry. Dentists never touch this class of child, and there is here no competition between the private practitioner and the public servant" (L.C.C. Med. Off. Educ., 1907). This adumbrated the school dental service before it had started. Now, I am equally certain that a dozen years hence there will be ten dental hygienists at work in the primary school to every registered dentist. Why try to stand in the way of progress? "It will be worse for the cow." The whole question does not affect dentists alone, nor is it a matter of dilution of labour, as I am afraid some of our friends may think. It is the development of small specialties of a somewhat expert nature, in a restricted field, for voluminous public services. The demand is there, it is urgent. If it is not met the prevention of disease remains still afar. But prevention cannot wait. It must be got in as full measure as is possible now. It must be general, it must be simple, it must be cheap, it must not be barred by any interests. So long as it suffices, and serious risks are negligible, we must not stand on ancient rights or pedantic formulæ.

The only solution of the general school, and it may be added pre-school, dental service, not for a tenth as at present but for all children, that at present offers itself is the employment of 10,000 comparatively cheaply trained but quite efficient dental hygienists in our primary schools, with a few of the more costly but fully trained dentists and doctors as the final controls. There are about 5000 names on the Dental Register, of whom about 3000 are fully trained. The sooner the end is attained the better for our public health, for in many places it is these hygienists or none. We must always inculcate that the preventive hygiene of the teeth is a matter in the first place for each single individual, and only in the last resort for a specialist.

I am, Sir, yours faithfully,
James Kerr.

Mecklenburgh-square, W.C., Oct. 20th, 1924.

THE SPAS IN TRANSITION.

A PLEA FOR A NATIONAL POLICY.

To the Editor of The Lancet.

Sir,—May I be allowed, as a convinced advocate of British waters, who has lately had an opportunity of investigating some of the chief spas in Italy and Switzerland, to offer to your readers the following notes and suggestions? The need for national stocktaking and reconstruction since the war has obliged those who are responsible for the spas of England to face the question, how these valuable health resorts may be best developed and utilised. Various interests are, of course, vitally concerned. I am dealing with the question simply as a neglected branch (as I believe) of medical science and practice. I venture to write you now because these latest impressions very greatly confirmed my opinion that a wise development at the spas as a whole is greatly needed in our country, and is indeed over-due.

1. *Specialisation of the Spa.*—At all the spas visited the special and individual characters of the water or baths are carefully defined, and the main indications (and contra-indications) for their medical use are prominently put forward. For instance, at Acqui the muds, and at Salsomaggiore the brines, are specially studied in their various applications. It follows that all forms of treatment, apart from the waters and baths, are considered of secondary importance.

N.B.—In former days there was a degree of specialism at the spas. In the last century a great many accessory methods were introduced, which in some places at home and abroad have obscured the original treatment. Consequently a very wide range of indications is now claimed for many spas. A reaction, however, has set in. It is clear that a rational and considered specialisation within the national group of spas is essential.

2. *The Practice of the Mineral Water Hospitals.*—These hospitals, such as the fine institutions at Salsomaggiore and Rheinfelden, show the same adherence to the main treatment and to the prescription of limited indications for its use. In these institutions accessory and surgical treatments are avoided, and one may watch, in cases of tuberculous glands or joints or bronchial asthma, the effects of treatment simply by brine baths or salt inhalations, &c.

N.B.—The Mineral Water Hospital affords the best available conditions for the study of the particular methods of the spa, used for selected cases and upon a large scale. It will be generally agreed that the results of treatment in these institutions are not adequately represented in medical literature. A standard system of measurements, records, and statistics for the British Spa Hospitals could no doubt be devised, and should prove of much scientific and practical utility. It is obvious that well-directed research in these hospitals is greatly needed in all countries.

3. *Official and Medical Control and Support.*—One or two of the principal spas in Italy are owned by the Government. The proper department supervises all spas, and confirms the appointment of the medical directors (vide infra). The national railways and the Italian Office of Tourism make a great contribution to the prosperity of the spas, and especially facilitate the visits of medical practitioners and students from home and abroad.

4. *Spa Practitioners.*—Every thermal establishment in Italy has its own medical director, who is responsible for all the treatment given. In addition to the medical directors, a body of consultant university professors is now attached to the Italian spas. In the new State Thermal Establishment at Salsomaggiore, for example, 12 consulting-rooms are provided for them and their assistants. They are selected as specialists in the maladies for which the local treatment is employed—e.g., diseases of the throat, of children and of women—and attend the spa regularly throughout the season.

N.B.—Such methods may bring increased prestige to the spa, and the directors certainly benefit by the coöperation of medical men of wide knowledge and experience. But can the visiting professor compete with the best local practitioner in his intimate knowledge of particular waters and baths? The results of this system will be awaited with interest, but the virtual disappearance of the old type of practitioner must be viewed with regret. For the reputation of many spas has been founded upon his experience.

5. *A New Specialism in Practice.*—There is arising a new order of specialists—not in the diseases that they treat, but in the remedies that they use. In the handling of baths and waters they are the acknowledged experts. In both medical and public opinion the spa is becoming a place for the exercise of the highest skill in certain forms of treatment. Each country has its own method. In France an increasing number ot practising hydrologists confine themselves to their specialty, and occupy the winter in travel, or studies at the various institutes of hydrology. In Italy no medical man can be appointed as medical director without a competent knowledge of this branch of treatment. It is the aim of the teachers of hydrology in continental universities to attract to this specialty a certain number of highly qualified men, and to give them facilities for the necessary theoretical and practical training.

N.B.—Specialisation in the treatment of incipient and chronic disease at the spas is an inevitable and wholly beneficial development. Each national group of spas offers an attractive field for clinical study and practice, and few men and localities may sometimes produce the finest work.

All the facts, in my judgment, point to the same nclusion. To meet the requirements of science d practice in England I would plead for a compre- nsive and national policy. Without entering upon tails, upon which my mind is entirely open, the uiding principles, as I conceive them, may be stated s follows: (1) the coördination and development of ritish waters, under medical authority; (2) post- aduate lectures in hydrology at the universities;) facilities at one university for the systematic aining of hydrologist practitioners. Much is said, d truly, about the need for research, but research turally follows the institution of teaching.

I am, Sir, yours faithfully,

London, Oct. 10th, 1924. R. FORTESCUE FOX.

FACT AND THEORY IN RADIO-THERAPY.

To the Editor of THE LANCET.

SIR,—I should like to assure Dr. Hernaman- hnson that I have not tried to read anything into s letter that I thought was not there.

1. I still cannot agree with him that in making the rong premiss that "unless a radiation penetrates the in it can have no effect on underlying organs," any ysical theory is disproved. That ultra-violet diation is very easily absorbed by the skin is a ysical fact, and the physical theory or theories which e linked with the phenomenon are those based upon e processes of molecular absorption. I do not think at any of these theories are weakened or disproved the statement cited, but we are both agreed that the asoning was wrong. I have only tried to make this int, because it seemed that for once theory was ally not at fault.

2. Animal tumours when removed from the body d given doses of X rays between transplantations come more resistant to X rays. Observations of is kind have not, for obvious reasons, been made on the human subject, so the rest is inference, and think we cannot carry actual conclusions further. agree with Dr. Hernaman-Johnson that in a mour mass we are dealing with cells in different ages of vulnerability towards radiation, but I ink that the studies on normal lethal doses show rtain limits over which this vulnerability extends, t that these limits are widely extended by the perimental process referred to.

3. Dr. Hernaman-Johnson is invariably generous his references to experimental work. He says that looks to experiments "to furnish new ideas which ay be tried out on actual patients." But then alas! cannot grant us so much, for a few lines later on read, "But when all this is admitted, one cannot ft' the results obtained for experiments on animals d apply them forthwith to the human subject."

I am, Sir, yours faithfully,

hysics Department, The Middlesex Hospital, W., Oct. 20th, 1924. SIDNEY RUSS.

CUPATIONAL DISEASES OF HOP-PICKING.

To the Editor of THE LANCET.

SIR,—I was interested to read Dr. W. J. Donovan's article in your issue of Sept. 20th scribing two cases of dermatitis from hop-picking d Dr. C. J. Streich's letter on the same subject a tnight later. I have seen several cases amongst the kers this season in South-West Kent. Dr. A. H. B. rkham, of Staplehurst, called me out to see a ubtful case of scarlet fever with him. The rash was upational, as the exposed parts only, particularly knees and wrist, were affected. On inquiry at the dical Mission hospitals and dispensaries quite a mber of such cases have been noted. Dr. B. E. den, who was in charge of the hoppers' hospital and pensaries in Marden district, states she noted cases. Another occupational disease in hoppers is te catarrhal conjunctivitis. I saw three severe cases of this affection. Both eyes were markedly infected, there was a copious purulent discharge and also distinct photophobia. Dr. Ebden reports 55 cases of this description. The condition is known amongst the pickers as "hoppers' eye"; the cases I noted were all children. Still another occupational affection I have observed is what is known as "hoppers' gout." I saw two cases of this under treatment at the Medical Mission at Horsmonden. The wrists, the joints coming directly in contact with the hops, were swollen and tender. There was no inflammatory condition of the skin in these cases.

These three occupational affections—dermatitis, conjunctivitis, and synovitis—are in my opinion, produced by some irritant from the hop plant. Generally they have been attributed to the chemical washes used on the plants, but in the present year, owing to the remarkable absence of "vermin" from the hops, no washes have been used. This points to the plant itself being the cause. The question is an interesting one and opens a field for investigation. Over 60,000 pickers come into South-West Kent every September. Their accommodation presents a serious problem, and there is much need for improvement in the type of dwellings provided and the sanitation of the same. Fortunately, concurrent with the past exceptionally bad season greater efforts have been made than hitherto by voluntary agencies to provide for the medical treatment and nursing of the pickers. New hospitals or dispensaries were opened at Marden by Mrs. Spender, at Horsmonden by the Hoppers' Medical Mission, and at Capel and East Farleigh by the Chelsea Branch of the British Red Cross. These alone report the treatment of 5061 cases with 8608 attendances. This is remarkable work for purely voluntary effort. Many of the workers are nurses or V.A.D.'s with war service. From my experience of the past two seasons there is ample room for more to follow the good example.

I am, Sir, yours faithfully,

S. NICOL GALBRAITH, M.B., D.P.H.,
M.O.H., South-West Kent.

Public Health Office, Tonbridge, Kent, Oct. 16th, 1924.

THE DANGER OF STRONG APPLICATIONS FOR OPHTHALMIA NEONATORUM.

To the Editor of THE LANCET.

SIR,—May I through your columns draw the attention of practitioners to the danger of continued use of strong applications in the prevention or treatment of ophthalmia neonatorum? Every year since St. Margaret's Hospital for ophthalmia neonatorum in London was opened by the Metropolitan Asylums Board there have been admitted two or three cases in which both corneæ have been destroyed or very severely damaged by the use of perchloride of mercury in strengths of 1–500 to 1–3000, used four or five times a day; or by nitrate of silver, 10 or 20 gr. ad ℥i. used as drops two or three times a day. Although these drugs properly applied in correct dilutions are satisfactory, there is great danger if they are not properly used. I therefore generally teach classes of midwives and others who attend this hospital to use protargol 10 per cent. or acriflavin 1–1500 in castor oil as both safe and effective in the prophylaxis and treatment of the disease.

I am, Sir, yours faithfully,

Harley-street, W., Oct. 16th, 1924. M. S. MAYOU.

QUERY DRUNK.

To the Editor of THE LANCET.

SIR,—Referring to the note in your issue of Oct. 11th (p. 771) on the magistrate who pressed a medical witness to say whether or not a man was "drunk," I remember this question was discussed some years ago when I was a divisional surgeon of police. Two definitions were then given; one, said to be in an Act of Parliament, ran thus : " A man is drunk if he has any sense or function impaired by the use of alcohol." This is, of course, much too strict for a non-prohibition country. The second, which I believe is the present standard for the Metropolitan police, is : " A man is drunk (in a police sense) if he is so under the influence of alcohol as to be a nuisance or a danger to himself or others." Needless to say, a man in charge of a horse and vehicle is a greater danger than if on foot, and one in charge of a motor-car a still greater danger than the driver of a horse-drawn vehicle, as the car has not even the brain of the animal. Of the many tests for " drunkenness " one of the best is for the suspected individual to try and stand on one foot with the eyes shut. In my time the divisional surgeons were instructed to say " drunk " or " sober," and not " under the influence of alcohol " or " has been drinking." But there were often troublesome cases, especially when the person's own doctor came and said he was sober.

I am, Sir, yours faithfully,
A. Charpentier,
Formerly Divisional Surgeon, X Division,
Jersey, Oct. 17th, 1924. Uxbridge Station.

THE CLINICAL THERMOMETER AS NOXA.

To the Editor of The Lancet.

Sir,—May I supplement your Annotation on the above (Oct. 18th) by pointing out the importance of *rubbing* the thermometer and not merely wiping it? Were we to trust more to friction there would be far less need for disinfectants, or for clinical thermometers which can be sterilised by heat.

I am, Sir, yours faithfully,
F. R. Walters.
Crooksbury Sanatorium, Oct. 20th, 1924.

Obituary.

JAMES ALBERT GIBSON, M.D. Edin., D.P.H. Irel., M.B.E.

Dr. James Albert Gibson, medical officer of health for the Isle of Wight Rural District, who died at King's College Hospital on Oct. 12th, at the age of 59, was a native of Aberdeen and received his early education at the Edinburgh High School. He studied medicine at King's College and University College, London, and graduated in medicine and surgery at the University of Edinburgh in 1889. After qualifying Dr. Gibson practised for a time at Hornsey, and held appointments under the Post Office, the Board of Education, and the Civil Service Commission. In 1906, having obtained the public health diploma of the Royal Colleges in Ireland, Dr. Gibson settled in the Isle of Wight, where he succeeded the late Dr Joseph Groves as medical officer of health for the Isle of Wight Rural District. Soon after he took up office the appointment of medical officers of health by county councils was made compulsory under the provision of the Housing, Town Planning, &c., Act, of 1909. It was generally believed that Dr. Gibson would be the first county medical officer of health for the Isle of Wight, and it was a great disappointment to him that he was not finally selected. The terms of the appointment, however, were not such as could be accepted by the medical profession at the time and he stood loyally by his colleagues. To those who knew him intimately any other course would have been impossible, and he had the satisfaction of knowing that his action was thoroughly appreciated. He threw himself with increased energy into his district work and carried out many reforms in characteristically unobtrusive though determined manner. He held the rank of captain *à la suite* in the R.A.M.C. Territorial Force, and during the war was specialist sanitary officer to the Portsmouth garrison. At the time of his death he was county director of the British Red Cross Society in the Isle of Wight. He also held the post of medical superintendent of the Isle of Wight Joint Hospital Board, and was at one time school medica officer of the Isle of Wight County Education Committee. A colleague writes of him : " He was a man of sound judgment, no lover of change merely for the sake of change, but when convinced that reforms wer due a very doughty opponent of the reactionary Through his death the public health service has los a highly competent and resourceful health reformer who will long be held in affectionate remembrance b those who were privileged to be among his friends.

Dr. Gibson was the author of several articles o public health and sanitary subjects.

JOHN HAMMOND MORGAN, F.R.C.S. Eng., C.V.O.

Mr. J. H. Morgan, consulting surgeon to Charin Cross Hospital, died recently in London in his seventy eighth year. He was a son of John Morgan, F.R.C.S and was born in 1847. He received his education a Harrow and Trinity College, Oxford, obtaining th degree of M.A. in 1873. His medical training wa given him by St George's Hospital, and he becam a Member of the Royal College of Surgeons in 187 gaining the Fellowship three years later. Aft continuing his studies for a time at Vienna, he becam surgical registrar to St. George's Hospital and subs quently assistant surgeon to the West Londo Hospital. Mr. Morgan specialised in the surgic diseases of children, and held many appointments this connexion ; he was surgeon to the Alexand Hospital for Hip Disease and to the Hospital f Sick Children, Great Ormond-street. When the Lo Mayor Treloar Cripples' Hospital was founded Alton some 17 years ago, Mr. Morgan was nominat a member of the original medical board, on the sugge tion of the then presidents of the Royal Colleges Physicians and Surgeons, and by the unanimous vo of his colleagues he was elected chairman of th board.

Sir Henry J. Gauvain writes of him as follow " It has been my great privilege to be intimate associated with Mr. John Morgan during the pa 16 years. In his work for the Lord Mayor Trelo Cripples' Hospital no one could have been more zealo in carrying out the duties his position entailed. the more urgent calls on his time diminished retained ever more keenly his interest in the work Alton. He was deeply interested in the advanc made in the technique of the treatment of o patients, and, tenacious to the sound principles which conservative treatment of surgical tuberculo are based, rejoiced in all advances made on these lin An ardent sportsman and a distinguished athlete (won the Inter-Varsity three miles three years in succe sion at Oxford and became President of O.U.A. his activities were limited of recent years by reason a severe accident in the hunting field. Neverthele till comparatively lately he managed to travel a gr deal, one of his latest considerable journeys be taken with his friend, the late Sir Frederick Trev to the West Indies. Since his retirement gardeni was one of his great hobbies. During the great he played his part while in his seventieth year medical chief of the Croix Rouge Hospital for wound soldiers at Nevers. He typified the old-fashion surgeon, dignified, courtly, with a high sense of d and a direct manner which concealed the kindest hearts and the most generous of instincts."

Mr. Morgan was at one time examiner in surg at the University of Oxford. He was a Knight Grace of the Order of St. John of Jerusalem in Engla a Companion of the Victorian Order, and recei the Médaille de Reconnaissance de la Républi Française. His publications include many papers various medical journals on surgical subjects. 1898 he was Lettsomian lecturer of the Medical Soci of London (and at one time was president of t society), his subject being the Surgical Affections the Urinary Tract of Children. To Heath's Diction

Surgery he contributed an article on Surgery of the nd. Other papers were Opening and Drainage of ints (*Guy's Hosp. Reports*, 1879) and the Treatment Traumatic Stricture (*Practitioner*, 1888).

ARLIAMENTARY ELECTION: MEDICAL CANDIDATES.

NOMINATIONS were completed on Oct. 18th, and e medical man has been returned unopposed to the use of Commons—namely, Prof. Thomas Sinclair, o represents Queen's University, Belfast, in the nservative interest. Prof. Sinclair was returned opposed for the same constituency at the General ection in 1923. The Scottish Universities constituy, which returned three members unopposed at the t election, is now being contested by four candidates. o of these, Sir George Berry and Sir Henry Craik, in the last Parliament. The latter, although not nedical man, has always been a good friend to dicine. The single seat for London University is ng contested by four candidates, three of whom medical men.

Polling takes place next Wednesday, Oct. 29th, when following medical candidates will submit themselves election. Those who sat in the last Parliament are icated by a dagger sign ; those who stood unsuccessly by an asterisk.

Candidate.	*Constituency.*	*Party.*

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—er the delivery on St. Luke's Day of the Harveian tion by Prof. Sir Archibald Garrod, the President, Sir mphry Rolleston, presented the Weber-Parkes Prize Medal to Prof. A. Calmette, formerly of Lille, now director of the Pasteur Institute, for his researches on erculosis. The President referred to him as the foremost hority on this subject, at the same time alluding to his arches into other aspects of bacteriology. He then sented the Moxon Gold Medal to Sir Leonard Rogers, .S., for his distinguished researches in clinical medicine. loing so, he remarked that there were few tropical diseases egard to which Sir Leonard Rogers had not laid the lical profession under debt by his investigations. He itioned especially dysentery, kala-azar, cholera, and osy, and wished him success in his present researches the treatment of tuberculosis.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, YAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL ULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The owing candidates having passed the requisite examinais have been admitted Diplomates in Public Health :—

eorge M. Currie, James L. Connacher, John Yule, Robert Lockhart, Thomas M. Hunter, Margaret W. Kemp, Margaret M. U. Martin, Robert Armstrong, Andrew Hamilton, Alexander King, Mary N. Hendry, Alice McGlashan, Annabella McGarrity, Thomas S. McKean, Anne M. Forrest, May Marshall, James D. Dear, Archibald Penman, Annie G. Learmonth, Elizabeth M. Lindsay, Percival V. Pritchard, Ian M. D. Grieve, Francis B. Mackenzie, Jenny C. King, Winifred Wight, Isobel C. Macdonald, Elizabeth M. J. Currie, Reginald J. Matthews, Sheila Hunter, Alexander M. M. Grierson, Frederick W. Gavin, George W. Simpson, Phyllis M. H. Lunn, Ganapathi S. K. Iyer, Jean V. Kirkwood, Robert H. Dunlop, Margaret D. Cairns, Catherine M. Buchanan, William H. Carter, Christina Grant, Daisy B. McBride, Charles C. I. Slorach, Isabella P. Crosbie, and John C. Macartney.

The following candidates have passed the Triple Qualification Examination :—

FINAL EXAMINATION.

Naranapillai Ampalavanar, Eric S. Brohier, Charles J. B. Cave, Teck Y. Chia, Fakherddin El Ahmadi, Adolphus S. P. Fernando, Eric C. Gilles, Patrick Groarke, Rodney H. Holt, Trevor Hughes, James K. Hunter, Herman H. James, Bentis S. Jayawardene, John W. Keighley, Thomas F. Kelly, Colin McCulloch, Lachlan MacLean, Roy N. Martin, David S. Middleton, Thomas J. Muir, Marcellin Perera, Kathirgamer Poothatanby, Frank P. Rust, William Rutherford, David Stewart, John P. Subramamiam, George H. Tarras, Victor B. van Dort, William G. S. Pepper, Velayutham P. Thiyagaraja, and John A. McCann.

Medicine.—Ebenezer A. M. McKinney, David Isaacs, Hapuarachige Don J. Lazarus, Petrus J. Badenhorst, Abraham M. Filer, and William A. D. Oliver.

Surgery. — Joseph F. Hedley, James M. Rutherford, Rajaratnam W. C. Thambiah, Ernest G. Douglas, and Petrus J. Badenhorst.

Midwifery.—Joseph F. Hedley, Mikhail Youakim, Arcot Vasudev, Florence M. Smith, Irma E. L. Mackenzie, Isaac Chesarkie, Marian E. Owen-Morris, Rajaratnam W. C. Thambiah, Ernest G. Douglas, John P. T. Mills, Abraham M. Filer, Nashid T. Yusif, Joseph Horsham, William M. B. Rossie, Henry A. Newton, and William A. D. Oliver.

Medical Jurisprudence.—Piang L. Low, Donald Ross, Charles E. Millen, Arcot Vasudev, James L. Malone, Andrew Wilson, Francis D. R. Wylie, Kripa R. Bali, John L. Clark, Gavin J. Bell, Harold B. Wainer, Hamilton J. Marcelin, John Sullivan, Arthur G. Farquharson, Peter King, Joseph W. McVicker, Mary A. McGill, James K. Steel, George M. Johnson, Appacuttiar B. C. Doray, William Allan, and James E. Kennedy.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College on Oct. 15th Sir Harold J. Stiles was re-elected President for the ensuing year, Sir David Wallace Vice-President, and Mr. Alexander Miles secretary and treasurer.—Mr. Pirie Watson was approved as a lecturer in surgery at the Extra-mural School.

The following 23 candidates (out of 54 entered) who passed the requisite examinations between July 7th and 11th, 1924, were admitted Fellows :—

Francis G. Bell, Alfred P. Bertwistle, Edgar S. Clayton, Avabai J. Dodhi, John A. Douglas, Alfred M. Elliott, Augustine S. Fry, Calansuria A. S. D. Jayanayake, Lachlan M. McKillop, Israel Maisels, Thomas M. Millar, John Miller, Hector M. Monro, Hector Mortimer, John R. Muir, Samuel L. Navaratnam, Forster H. B. Norrie, Tharamale G. R. Panikkar, John W. Riddoch, Richard H. Rose-Innes, Harish C. Suri, William P. Tew, and Douglas St. J. Wigle.

UNIVERSITY OF DUBLIN, SCHOOL OF PHYSIC, TRINITY COLLEGE.—At recent examinations the following candidates were successful :—

FINAL MEDICAL EXAMINATION.

Part I., Materia Medica and Therapeutics ; Medical Jurisprudence and Hygiene ; Pathology and Bacteriology.—Seymour F. Heatley (passed on high marks), Margaret H. Donaldson, Nancie N. Lowther, Samuel Smyth, William P. Cuthbertson, William Magowan, James C. C. Boyle, Ernest E. Satchwell, Herbert A. Brittain, Robert Kahn, George A. Walmsley, Wilfred Sinclair, Douglas Bluett, Mabel E. Brittain, Aileen Fair, Jane D. Fulton, William R. G. Gallagher, Gerald V. A. Griffith, Ernest H. Hall, Victor G. Horan, Ernest E. Malone, Harry Nelson, Andrew E. A. O'Byrne, Frances E. O'Connor, Philip F. Palmer, Grace J. Rankin, Stella C. Ross, William Russell, John C. T. Sanctuary, Lionel B. Somerville-Large, Hope Trant, Richard T. P. Tweedy, Edmund J. Walsh, and Charles F. M. Wilson.

DIPLOMA IN PUBLIC HEALTH.

Part I., Chemistry, Bacteriology, Physics, and Meteorology.—Kundanmal J. Bhavnani, John M. Gray, and William T. Hogan.

Part II., Sanitary Engineering ; Practical Sanitary Report ; Hygiene and Epidemiology ; Vital Statistics and Sanitary Law.—Edward Parker and Kundanmal J. Bhavnani.

DIPLOMA IN GYNÆCOLOGY AND OBSTETRICS.

Cecil C. Coghlan.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At the annual meeting of the Royal College of Physicians, held on St. Luke's Day, Sir William John Thompson was elected President. Sir William Thompson has been a Fellow of the College since 1902, and has served in the usual offices of censor and examiner. As senior censor and Vice-President for the past two years he has, owing to the continued illness of the outgoing President, had to perform many of the duties which ordinarily fall to the President. Formerly physician to Jervis Street Hospital, Sir William Thompson has been, since 1908, Registrar-General, first of Ireland, and latterly of the Irish Free State. He has declared that it is not his intention to hold the office of President for more than one year, in view of the fact that he is a Civil servant. In this he follows the precedent of the late Dr. T. W. Grimshaw, who was elected President of the College while holding the office of Registrar-General. The censors of the College elected on St. Luke's Day are:—In medicine: Drs. G. E. Nesbitt and R. J. Rowlette; in medical jurisprudence: Dr. W. A. Winter; in midwifery: Dr. G. FitzGibbon. The President nominated Dr. Winter as Vice-President. At the same meeting two new Fellows were elected: Dr. Mary E. T. Hearn, of Cork, and Major J. D. Sandes, of the Indian Medical Service. Dr. Hearn is the first woman to be elected a Fellow of the College, which, nearly 50 years ago, was the first educational body in the three countries to admit women as licentiates.

Rontgen Society.—A general meeting of this society will be held on Tuesday, Nov. 4th, at 8.15 P.M., in the British Institute of Radiology, 32, Welbeck-street, London, W. 1, when the presidential address will be delivered by Dr. A. E. Barclay, the subject being the Growth of Radiology: Has the Rontgen Society kept pace with it?

Royal Commission on National Health Insurance.—This Commission held its second meeting on Oct. 15th at the offices of the Ministry of Health, Whitehall. Before proceeding to the taking of oral evidence the Commission considered the question of admission of the public and the press to the meetings at which such evidence would be taken. The Commission decided that the meetings should be held in private, but that a short summary of the business done should be communicated to the press immediately after each meeting, and that a verbatim report of the evidence should be published and placed on sale through the Stationery Office within about a fortnight after the date of the meeting at which it had been taken. Thereafter the Commission proceeded with the evidence of Sir Walter Kinnear, Controller of the Insurance Department of the Ministry of Health, who was questioned on the law and administration of the Health Insurance Scheme in its present form. Sir Walter Kinnear's evidence was not concluded when the Commission rose for the day, and he was to be heard further on Oct. 23rd.

Society of M.O.H.'s: Annual Dinner.—The annual dinner of the Society of Medical Officers of Health was held at the Hotel Cecil, London, on Friday, Oct. 17th, the President, Dr. Robert A. Lyster, being in the chair. There was a large attendance of health officers and their friends from all parts of the country, about 130 guests sitting down to dinner. The toast of "The Society" was proposed by the Bishop of Winchester, who described the medical officer of health as the life-preserver of the community and one who was always proposing the health of his municipality. He spoke feelingly of the housing conditions in urban areas and of the pressing need not only to make houses fit for heroes to live in but to make heroes fit to live in them. Dr. Lyster, in reply, said that no one would welcome more heartily the powerful aid of the Church than the public health service, and, as a matter of fact, close relation had existed between them for centuries. He quoted the dictionary definition of "Society" as a noun of multitude signifying "many" but not signifying "much," paying a tribute to Prof. Kenwood's successful effort to make that Society count for something during his prolonged tenure of the presidency. The public health branch of medicine saved life by thousands where the curative branch did so by individuals, and it was evidently the leading branch of medicine for the future. Dr. G. F. Buchan proposed "The Ministry of Health" and emphasised the need for coördination in order that British public health administration might remain the shining light among the nations that it now is. Sir Arthur Robinson, in reply, recited the multifarious activities of the Ministry, including such branches as the care of canal boats and insurance practice. It was the aim of the Ministry, he said, to get hold of all these principles by the health end. Prof. Harold Kerr proposed "The Guests," response being made by Lord Dawson of Penn, Sir Humphry Rolleston, Sir Francis Champneys, and Mr. H. J. Waring. "The President" was proposed by Dr. Lockhart Stephens, who put in a plea for the part-timer as a liaison officer between the public health authority and the general practitioner; and Dr. Lyster, in thanking the gathering for its warm reception of him, said he had never heard a word of animosity on the part of any medical officer of health against the part-timer; he did splendid work, and it was only the conditions under which he worked which required remodelling. Dr. Herbert Jones proposed "The Executive Secretary," and Mr. G. S. Elliston briefly replied. Excellent vocal music was provided during the evening by Miss Olive Sturgess and Mr. Norman Williams.

Naval Medical Compassionate Fund.—At th quarterly meeting of the directors of this Fund, held o Oct. 7th, Surgeon Vice-Admiral Joseph Chambers, C.B C.M.G., R.N., Medical Director-General of the Navy, in th chair, the sum of £69 was distributed among the sever applicants.

Aberdeen University Club, London.—Th bi-annual dinner of this club will be held at Gatti Restaurant, Strand, on Thursday, Nov. 6th, at 7.30 P.M On this occasion the George MacDonald centenary will celebrated. Dr. W. A. Milligan, 11, Upper Brook-street, W will be glad to hear from past or present graduates, m or women, wishing to attend the dinner or join the club.

Instruction to Pupil Midwives.—An instructio course, open to all midwives teaching pupils midwifer will be held by the Association of Teachers of Midwife at the Royal Society of Arts, John-street, Adelphi, W.C. on Oct. 29th, 30th, and 31st. Five lectures or demonstratio will be given each day, and among the lecturers are Dr. Lane-Claypon, Dr. J. H. Sequeira, Prof. L. McIlroy, Pr Winifred Cullis, Prof. T. B. Johnston, Dr. Harold Wall Mr. Farquhar Murray, and Dr. J. S. Fairbairn. Furth particulars may be obtained from the Secretary of th Midwives' Institute, 12, Buckingham-street, Strand, W.C.

Warren Triennial Prize.—This prize was found at the Massachusetts General Hospital, U.S.A., by the la Dr. J. Mason Warren in memory of his father, and will provides that the accumulated interest of the fu shall be awarded every three years to the best dissertati considered worthy of a premium, on some subject physiology, surgery, or pathological anatomy, the arbitrat being the General Executive Committee of the Massachuse General Hospital. Theses submitted for competition for t year 1925 shall be on some special subject in physiolo surgery, or pathology, and must be typewritten in eit English, French, or German. The amount of the prize the year 1925 will be $500. Dissertations will be receiv until April 15th, 1925.

Liverpool Medical Institution.—The inaugu meeting of the eighty-sixth session of the Institution w held on Oct. 16th, when there was the large attendance 170 members. The chair was taken by Mr. R. C. D the President, who referred to the death during the year three members of the Institution, Mr. Newbolt, Dr. G and Dr. De Jong. He also alluded to the steady increa of membership of the Institution. His inaugural addr was entitled "The Banner of Our Pride," in which sketched the ancient history of the Order of St. John Jerusalem in the Mediterranean and in England. T development of first-aid work through the agencies of t St. John Ambulance Association and Brigade was explain and also the origin and pre-war work of the British Cross Society. The war work of these two great organisatio combined in a joint war committee was illustrated many extracts from the official report. In conclusion, was shown how, through the ages, the ideals of those w had worked under the white or the red cross flag h remained the same and how that work had been for coun and for humanity.

Medical Sickness, Annuity, and Life Assuran Society.—Dr. F. J. Allan, who presided at the ann general meeting held at 300, High Holborn, London, W on Oct. 6th, called attention to the flourishing condition the society, which is now in its fortieth year. annual report for the year ending June 30th, 19 shows that the total premium income amounts £53,969, and the average rate of interest earned £4 16s. per cent. gross, and £4 0s. 11d. per cent. after ded tion of tax. The Sickness and Accident Fund the Life Assurance Fund have increased by £24,479, amount to £373,710. The number of policies issued by Sickness and Accident Fund was 433 for annual premi of £5037 17s. 10d. Sickness claims paid amounted £24,131 19s. 6d. The total premiums amounted £41,582 16s. 4d. The total of the fund at close of pe was £263,963 11s. 9d. The number of policies issued the Life Assurance Fund was 234, assuring £139,660 gr and £137,360 after deduction of reassurances, for net an premiums of £4446. The premiums amounted to £12, while the claims by death and maturity amounted £4950. The surrenders were £206 16s. 9d., and the annui paid £5330. The number of annuitants who died were and by these deaths annuities to the amount of £250 h ceased to be payable. The total of the fund at the of the period was £109,746. The report being adop Dr. C. Buttar and Dr. H. Hilliard were re-elected mem of the board of directors. A vote of thanks to chairman, proposed by Sir William Willcox, concluded proceedings.

MEDICAL LORD MAYOR.—Dr. George Stevens Pope s been selected as the new Lord Mayor of Norwich.

THE Hon. Herbert Crawshay Bailey, Barrister-at- v, has been appointed as Commissioner of the Board of ntrol in succession to the late Mr. A. H. Trevor.

LONDON COUNTY COUNCIL MEDICAL SERVICE.—It s been decided that for the future medical women in the vice of the L.C.C. shall resign on marriage. This rule ll not apply to the three married women medical officers present serving the Council.

ROYAL NORTHERN HOSPITAL.—Princess Louise, chess of Argyll, will open the new nurses' home on t. 30th at 3.30 P.M. The home is the first section of a ger building, and provides separate bedrooms for nurses and administrative offices, sitting-rooms, &c., for complete building, which will eventually accommodate ly 120 nurses.

UNIVERSITY OF BRISTOL: ASSOCIATION OF ALUMNI ONDON BRANCH).—The annual dinner of this branch will held on Friday, Nov. 7th, at 7.30 for 7.45 P.M., at Pagani's, -48, Great Portland-street, W. Lord Haldane will preside. mbers of the University and past members of its associated leges are invited to apply early for tickets, price 8*s.* 6*d.* clusive of wines), to the hon. secretary, Holloway natorium, Virginia Water.

ALTON COTTAGE HOSPITAL.—On Saturday, Oct. 18th, the presence of a large gathering, the new extensions to hospital were opened, in the absence of Major-General Rt. Hon. J. E. B. Seely, by Canon Causton, Master St. Cross, Winchester, whose father founded the spital. The ceremony of dedication of the wards d operation theatre was performed by the Rev. J. D. rter. The enlargement of the Institution consists of two w wards with accommodation for 16 extra beds, a surgeon's m and lobby, anæsthetic and sterilising rooms, a matron's m, an operation theatre, and two private wards. In dition there is a block for X ray treatment, an out-patient partment, and a new power house for lighting and heating rposes. The extensions, which cost some £18,000, were de possible through the generosity of Mr. and Mrs. F. B. mmers, of Froyle-place, Hants, in memory of their two ldren. Mr. Summers, who is chairman of the hospital nmittee, presided at the opening ceremony.

DONATIONS AND BEQUESTS.—The Royal Cornwall firmary will benefit under the will of the late Mr. John mes, of Truro, by a sum of £1000.—By the will of the late George Heaton, F.R.C.S., of Sutton Coldfield, Warwick- re, the testator left £1000 to the Birmingham General spital upon trust for investment, and to pay the income nually as to one-half to the person whom the medical mmittee of that hospital shall decide to be the best resident alified officer of that hospital for the year. He desired at in making such decision the committee should take o account not only the academical qualifications of that icer, but also his or her industry, attention to duties, nsideration for patients, and general disposition and rsonal character, so that the recipient shall be the best icer from the general point of view. One-fourth to the ter or staff nurse whom the matron (being guided as above) all decide to be the best of the year. One-fourth to the ter or staff nurse selected by vote of the whole of the ters, nurses, and probationers of the hospital.—Mr. fred Langton, chairman of the Hampstead General spital, has given that institution a new X ray depart- nt.—A cheque for £1500 has been presented to the yal Victoria and West Hants Hospital by the Executive d Carnival Committees of the Bournemouth Hospital turday and Sunday Fund; £1000 of this amount has been marked for the extension scheme fund of Boscombe spital.—Alderman John Pennington Waters, J.P., ngston Hill, Surrey, left £200 each to the Kingston ctoria Hospital, the Kingston Nursing Association, Kingston Day Nursery, the Association for Pre- ntive and Rescue Work, and the Central Aid Society.— James Brindley Sherwin, Tottenham, left £200 ch to the Prince of Wales's Hospital, Tottenham, and Middlesex Hospital, and £100 to the Mothers' Lying-in me.—Mr. George Aspinall Jackson, of Bradford, left 00 each to the Bradford Royal Infirmary, the Bradford ildren's Hospital, and the Bradford Nurses' Institution.— William Harrap Mason, of Leeds, surgeon, who left 9,115, bequeathed £1000 each to the Leeds General firmary and to Dr. Barnardo's Homes; £500 each to the eds Public Dispensary, the Hospital for Women and ildren, Leeds; and £250 to St. Peter's Church, Dewsbury, the poor at Christmas. Subject to a few legacies, he t the residue of the property to such Leeds charities as executors should select.

JUNIOR EDINBURGH CLUB IN LONDON.—The first dinner for the winter will be held at the Boulogne Restaurant, Soho, on Friday, Oct. 31st, at 7.30 P.M. Informal dinners are held monthly, and membership is open to all recent graduates of Edinburgh University. The hon. secretary is Dr. R. Scott Stevenson, 30, New Cavendish-street, W. 1.

UNIVERSITY OF SHEFFIELD.—A course of six lectures on the History of Medicine will be given by Mr. George Wilkinson during the winter session. On Oct. 31st he will speak on the Mediæval Practitioner, Chaucer's "Doctour of Phisyk"; on Nov. 14th the beginnings of the application of Physics to Medicine will be discussed, with special reference to Descartes, Borelli, and Boerhaave, and on Nov. 28th the beginnings of the application of Chemistry to Medicine (Paracelsus, Van Helmont, Franciscus Sylvius). On Jan. 30th, 1925, the lecturer will trace the History of the Microscope, and on Feb. 13th the beginnings of its application to Medicine (Malpighi). The final lecture on Feb. 27th will be devoted to the origin of the "germ theory" of disease. The lectures will be at 4.30 P.M. They are open to University students and to medical practitioners.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Oct. 27th.

ODONTOLOGY: at 8 P.M.
Presidential Address by Mr. J. G. Turner.
Paper:
Mr. E. D. D. Davis: Some Points in the Pathology, Diagnosis, and Treatment of Diseases of the Maxillary Antrum.

Tuesday, Oct. 28th.

MEDICINE: at 5.30 P.M.
Clinical Meeting at Charing Cross Hospital, W.C. Tea will be served at 5 P.M.

Thursday, Oct. 30th.

UROLOGY: at 8.30 P.M.
Presidential Address:
Mr. C. A. R. Nitch: Renal Tuberculosis.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Oct. 27th.—8 P.M., Clinical Evening: Exhibition of Cases and Skiagrams. (Cases will be on view from 8 to 9 P.M.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
FRIDAY, Oct. 31st.—5 P.M., Prof. Arthur Keith: Museum Demonstration: Specimens illustrating Points in the Applied Anatomy of the Heart.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Oct. 27th, to SATURDAY, Nov. 1st.—WEST LECTURE HALL, Royal Society of Medicine, 1, Wimpole-street. Lectures arranged by the FELLOWSHIP OF MEDICINE and open to all members of the Profession. At 5.30 P.M., Wed., Oct. 29th, Mr. Sampson Handley: Cancer of the Breast. Fri., Oct. 31st, Mr. R. H. Jocelyn Swan: Malignant Growths of the Kidney.—CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C. Special Intensive Course, third week. LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Endsleigh-gardens. Tues. and Thurs., at 2 P.M., Clinical Demonstration by Dr. G. C. Low and Dr. Manson-Bahr.—ROYAL FREE HOSPITAL, Gray's Inn-road, W.C. Wed., 5.15 P.M., Dr. Heald: Lecture-Demonstration: The Uses of Other Electrical Currents.—HAMPSTEAD GENERAL HOSPITAL, Haverstock-hill, N.W. Special Intensive Course in General Medicine and Surgery, first week.—DISEASES OF CHILDREN (COMBINED COURSE) at the Paddington Green Children's Hospital, Victoria Hospital, and Children's Clinic. Special Intensive Course, first week.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
TUESDAY, Oct. 28th.—4.30 P.M., Dr. L. R. Yealland: Syphilis of the Central Nervous System.
FRIDAY.—4.30 P.M., Dr. C. E. Sundell: The Rheumatic Child.
Daily: Medical and Surgical Clinics, Clinics in the various Special Departments, Surgical Operations, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, Oct. 27th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards. 2 P.M., Mr. Bishop Harman: Eye Dept.

TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Banks-Davis: Throat, Nose and Ear Dept.

WEDNESDAY.—11 A.M., Medical Registrar: Medical Wards. 12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—12 noon, Dr. Scott Pinchin: Diseases of the Heart. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

FRIDAY.—10 A.M., Mr. Simson: Gynæcological Operations. 12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Dr. Burrell: Medical Out-patients.

SATURDAY, Nov. 1st.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, Oct. 30th.—4 P.M., Dr. Nabarro: The Bone and Joint Lesions in Congenital Syphilis.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.

TUESDAY, Oct. 28th.—5 P.M., Dr. H. W. Barber: Immunity. Anaphylaxis.

THURSDAY.—5 P.M., Dr. W. Griffith: Principles of Treatment. General.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)

WEDNESDAY, Oct. 29th.—(At the Northern Hospital). Mr. Hugh Reid: Head Injuries.

THURSDAY.—(At the Stanley Hospital.) Mr. Courtenay Yorke: Ear, Nose, and Throat Cases.

FRIDAY.—(At the Royal Infirmary.) Mr. Thelwall Thomas: Surgical Cases.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

TUESDAY, Oct. 28th.—4.15 P.M., Mr. C. Roberts: Empyema.

FRIDAY.—4.15 P.M., Prof. W. W. C. Topley: The Control of Diphtheria by means of the Schick Test.

UNIVERSITY OF SHEFFIELD POST-GRADUATE LECTURES. (At 3.30 P.M.)

TUESDAY, Oct. 28th.—(At the Royal Infirmary.) Mr. W. S. Kerr: Diseased Tonsils.

FRIDAY.—(At the Royal Hospital.) Prof. A. J. Hall: Some Sequelæ of Epidemic Encephalitis.

ROYAL INSTITUTE OF PUBLIC HEALTH, Russell-square, W.C.

(Course of Lectures on the Health of the Commonwealth.)

WEDNESDAY, Oct. 29th.—4 P.M., Dr. C. W. Saleeby: Helio-Hygiene.

THE PEOPLE'S LEAGUE OF HEALTH. Course of Lectures on the Mind and What We Ought to Know About It.

(At the Medical Society of London, 11, Chandos-street, W.)

MONDAY, Oct. 27th.—6 P.M., Dr. Thomas Beaton: Sensation, Perception, Ideation, and Memory.

Appointments.

Paddington Green Children's Hospital: WILLIAMSON, B., M.B., Ch.B. Edin., has been appointed House Physician; HALLEY, G. S., M.B., Ch.B. St. And., House Surgeon.

Certifying Surgeons under the Factory and Workshop Acts: JONES, F. C., L.R.C.P. Lond., M.R.C.S., Cwmbran, Monmouth; PARIS, W., L.R.C.P. & S. Edin., L.R.F.P.S. Glasg., Kirkwall, Orkney.

Vacancies.

For further information refer to the advertisement columns.

Bolton Union, Townleys Hospital, Farnworth.—Second Asst. M.O. £225.

Bradford Children's Hospital.—H.S. £100.

Bradford Royal Eye and Ear Hospital.—H.S. £120.

Bristol University.—Directorship of Clinical Obstetrics.

British Honduras.—Asst. M.O. $2430.

Burnley Union, Primrose Bank Institution.—Res. M.O. £300.

Cancer Hospital, Fulham-road, S.W.—H.S. for six months at rate of £100. Also Anæsthetist.

Canterbury, Kent, and Canterbury Hospital.—Third Res. M.O. £125.

Cape Town University.—Wernher Beit Chair of Pathology

Countess of Dufferin's Fund, Women's Medical Service for India.—Two Med. Women. Rs.550.

Gesto Hospital, Edinbane, Skye.—Res. M.O. £300.

Hampshire County Council.—Dental S. £500.

Hospital of St. John and St. Elizabeth, 40, Grove End-road, N.W.—Second Res. M.O. for six months at rate of £100.

Hull, City and County of Kingston-upon-Hull.—M.O.H. £1400.

Leicester, Isolation Hospital and Sanatorium, Groby-road.—Res. M.O. £350.

Leicester Royal Infirmary.—Hon. Radiologist. 100 guineas.

Lincoln, Lindsey County Council.—Third Dentist. £500.

London Hospital, E.—First Asst. to one of the four Med. Firms £400.

London Royal Free Hospital School of Medicine for Women, Hunter-street, Brunswick-square, W.C.—Third Asst. in Obstet. and Gynæcol. Dept. £270.

Metropolitan Asylums Board Infectious Hospital Service.—Jun. Asst. M.O.'s. £500.

Newport Education Committee.—Asst. Dentist. £450.

Oswestry, Shropshire Orthopædic Hospital.—Two H.S.'s. Each £250.

Pendleton, Municipal Maternity and Babies Hospital, Seedley-terrace.—Asst. Child Welfare M.O. £608 8s.

Plymouth County Borough.—M.O.H., &c. £1200.

Poplar Hospital for Accidents, East India Dock-road, E.—Sen. Res. O. £200.

Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Two Asst. Res. M.O.'s for four months at rate of £80. Also Sen. R.M.O. £100.

Queen's Hospital for Children, Hackney-road, E.—Phys. in charge of Skin Dept.

Reading, Royal Berkshire Hospital.—Hon. S.

Rochester, St. Bartholomew's Hospital.—Res. H.S. for six months £250.

Royal Chest Hospital, City-road, E.C.—P.

Royal Eye Hospital, St. George's Circus, S.E.—Hon. Asst. S Also Clin. Assts.

Royal Naval Medical Service.—Surg. Lieuts. 25s. per day.

St. John's Hospital for Diseases of the Skin, Leicester-square, W.C—Clin. Assts.

St. Mary's Hospital, W.—Director of the Dept. of General an Special Pathology, &c. £800.

St. Mary's Hospital for Women and Children, Plaistow, E.—Res M.O., and Asst. Res. M.O. for six months at rate of £175 an £130 respectively.

Swansea General and Eye Hospital.—H.P. £175.

West London Hospital, Hammersmith-road, W.—Surg. for Dis. o Women. Dermatologist. Also Hon. Medical Radiologis

The Chief Inspector of Factories, Home Office, London, S.W announces the following vacant appointments: Bethn Green, London; Aberayron, Cardigan; Coggeshall, Esse

Births, Marriages, and Deaths

BIRTHS.

DAGGER.—On Oct. 13th, at 14, Howard-road, Morpeth, Nor umberland, the wife of R. Leslie Dagger, M.D., M.R.C. of a daughter.

PURVIS.—On Oct. 17th, at Strathnaver, Helensburgh, th wife of Major M. Purvis, Indian Medical Service, of daughter.

WYNN PARRY.—On Oct. 14th, at Denison Hall, Leeds, to M and Mrs. Henry Wynn Parry, a son. Grandson of M and Mrs. R. H. Parry, of Glasgow, and Sir Berkeley an Lady Moynihan, Leeds.

MARRIAGES.

COLLEY—THOMAS.—On Oct. 17th, 1924, at St. Michael's, Woo Green, London, Thomas Colley, F.R.C.S., younger son Mr. Thomas Colley and Mrs. T. Colley, of Preston, to Elean Mary, elder daughter of the Rev. Principal D. J. Thoma O.B.E., M.A., J.P., and Mrs. D. J. Thomas, of the Traini College, Wood Green.

HAWLEY—SANGUINETTI.—On Oct. 15th, at St. John's, Stanmor Arthur Thomas Hawley, F.R.C.S. Edin., to Joyce Myfanw Sanguinetti, only daughter of Mrs. Sanguinetti, of The Wy Elms, Stanmore.

DEATHS.

FOSTER.—On Oct. 13th, at Quetta, Ena Dorothy Foste M.R.C.S., L.R.C.P.

WOOD.—On Oct. 18th, at Southernhaye, Lyme Regis, Willia Edward Ramsden Wood, M.D., aged 75.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices Births, Marriages, and Deaths.

CEYLON MEDICAL DEPARTMENT.—At the closi session of the Ceylon Legislative Council on August 28 the Governor, Sir William Manning, said that t medical department of the colony had expanded ve considerably during the last three years. In 1921 t expenditure was Rs.5,093,889, while in 1924 it w Rs.7,448,600. In 1921 the expenditure on medical resear was Rs.600; to-day it was Rs.70,142. 1,500,000 perso have been treated for ankylostomiasis in this perio For the treatment of parangi, the Ceylonese form of yaw nine whole-time medical officers are employed, one in ea province. Ten new hospitals and 33 new dispensari have been opened, and additions and improvements 40 hospitals have been made. A malariologist has be appointed with a staff to assist him; sanitation has be seriously taken up, and four medical officers of health a 65 sanitary inspectors appointed. For estate medic inspection six whole-time officers have been appoint The department has shared in the general developme which has taken place during the period 1921–24, and record of advancement is very satisfactory. Ceylon, t Governor concluded, is better supplied with hospitals a dispensaries than any other tropical colony.

Notes, Comments, and Abstracts.

MEDICINE IN A CORNER OF THE EMPIRE.

An Address Delivered at the Social Evening of the Royal Society of Medicine on Oct. 16th, 1924,

BY DR. W. T. GRENFELL, C.M.G.

I HAVE been wondering why the Royal Society of Medicine were interested in my proceedings in so far off a portion of the Empire. The only solution I could come to was that as they are prolonging life so much they are looking out for parts of the world to be developed for people to go and live in them. I was told to-day that the East is getting so tired of the West that they are going to push us back again, and that there would not be standing room in England if they were going to increase the longevity of its people. I hope, on that score, that you will feel a little increased interest in a country which was called, when I went there, "The dump-heap of the earth."

Labrador.

I hardly know what line to take in speaking to the Royal Society of Medicine. Of course, if you are face to face with concrete problems such as we have in Labrador, which take all your time and energies, you realise from the beginning that, as far as medicine and surgery go, there will be very little opportunity to discover a disease, much less a cure for it. So I have always been a kind of parasite on the profession in that way; and when we have a disease which we do not know anything about, one of us goes roaming to see if anybody else does. It is to gentlemen like yourselves and others that we have often had to come. During the 30 years I have been in Labrador we have come once or twice, with very great advantage to our people. So I assure you I am not only honoured at being asked to speak to-night, but I realise the enormous debt of gratitude we owe to these centres of civilisation, to the great advances they have freely given to the world outside, not less on this side of the water than on the other. I know that though we think sometimes of the Americans as a concrete whole, those who are over there realise that the Anglo-Saxon part of the population on the other side is closely united in sympathy and sentiment and everything else to us.

Labrador is the nearest part of the North American Continent to England. You have only to, as it were, walk straight across, and you walk into my hospital; you do not walk into the United States, nor even into Canada, you walk into a country that is maintaining the kind of community that gave England her place in the world that she occupies to-day: men who go down to the sea in ships. These schooners, as far south as Gloucester and the main Nova Scotian coast, and as far as Newfoundland, are manned by the very same type as followed Drake and Raleigh, and all the admirals down to Nelson, who fought for our liberty and freedom in sailing ships on the high seas. The men of Labrador are English seamen. That is one of the reasons why I stay there; I like the people, and I think we are giving them a chance which they never had before.

Pioneers of all races have almost always had very short-sighted visions of the capacities of countries which do not give an immediate return. We once wanted to trade Canada for a single West Indian island because Canada was never going to be any use. Most people have but the vaguest idea as to where Labrador is. The man who got nearest to it was a man I heard praying for Labrador one day, and, as people who say prayers do, giving some information to the Almighty. And he began to tell Him the boundaries of Labrador. But he got mixed up and wound up with: "God knows where that is." It is not very long ago that I spoke to a man who certainly had had opportunities to learn better, and who said he thought it was an island in the Gulf of Mexico! I am sure of this, that a section of continent with something like half a million square miles of land must, from the very fact that it is so large, have something to give back to civilisation.

When I first saw Labrador, it was from the deck of a 99-ton boat on which I had sailed across the Atlantic, and I cruised for three months between Greenland and Labrador. I had a small hospital on board, carrying six beds, and only an untrained male nurse. I did not know whom I was going to see, and I did not expect to see land. We fell in with a fleet sailing between Hudson Bay and Greenland, and I cruised with them. At the end of that time we had had about 900 patients. As the sea froze up in November and I had no means of wintering, I sailed back home.

Operating under Difficulties.

In Labrador the crassest of ignorance was causing death and suffering to a people that I often feel like taking my hat off to, because they are real men. And yet I have been able to do so little. What could you do? I have operated on the beach several times. I had some anæsthetics and so on with me, but these people did not like anæsthetics; they were like the men who, when chloroform was discovered, thought it was wrong to relieve people of pain, and so they put up with the pain. I remember to-day a woman with a very large incapacitating tumour in the leg. I offered to remove it for her, but she would not have an anæsthetic, and as I was quite alone I did not feel like doing it. But next morning she was aboard with six huge fishermen, and when I asked what they wanted, they said they had come to sit on the woman while I operated. The problems you are up against are largely those which give pleasure in the solving. If the joy of life is solving problems and feeling you have done something, then in Labrador you can have a good time. Owing to invitations of different people, and as help had been promised me, I made up my mind to go back again. I went to the London Hospital and told some of the nurses that I could not do justice to the people in any way without a nurse of some kind. The first two nurses I appealed to, though they had easy, remunerative, and sure jobs, offered to come with me, and sailed in the spring. I say that because I have offered nurses every kind of job for 40 years, and have never had them say No. I sent a nurse, some years ago, to a village 60 miles from hospital, and she was cut off from me by a break-up of the sea ice. We had a wire round the bottom of the bay, and I got a wire from her one day that a man had gone out of his mind and had ripped his bowel open. He had hyperpyrexia, and his bowels got mixed up with the hay he had in his cottage. He had picked up his bowels and walked into her house, and she wanted to know what to do. There was very little I could tell her over the wire; practically all I could say was, "Do the best you can." Six weeks later, when the boats came North, I saw a boat approaching, one of the long open trap boats which we had closed in and fitted up with a stove, and on it was the nurse and two patients. One was the man who had disembowelled himself. The nurse told me how she had tackled the case. She had some chloroform and she went to the Catholic priest. They talked about the case, and she said she had never done an operation in her life, nor had he. They agreed that if the priest would give the viaticum first, it would not matter so much. I can only say, as an illustration of the splendid class of patients I have to operate on, that when they brought the patient in, he was almost entirely cured, and he is working as a fisherman to-day.

Epidiascope Demonstration.

Dr. Grenfell then showed with the epidiascope a series of colour photographs depicting the life and customs of the people and the grandeur of the country's scenery. By means of a map he explained the relative position of the country, and said it was kept cold by the Polar current washing its shores. Little or nothing seemed to have been known when he first went there about the physiography and geology of Labrador, and he instituted a sort of symposium of knowledge which was available about it. There were no reliable charts to steer by; even those places marked on the map were not dependable. A day would come, he said, when the fiords—more beautiful than those of Norway, would prove a great attraction. The rivers were full of the most unsophisticated salmon and trout in the world. The cliffs were in some places 4000 feet high at the water's edge, and were an outcrop of the Appalachian Mountains. The valleys were filled with trees, which each year became larger and more valuable. Arrangements had been made to establish a hospital, as it was felt the people should have a place to make for in time of need. A wireless installation, one of the first in the country, was put up, and this was a great help, as the Government had three stations, 200 miles apart, whence calls from patients could be received.

Dr. Grenfell concluded by a reference to prohibition. Before this era there had been a great deal of neglect and impoverishment, especially of the children, as men would often drink away in a couple of days the profits they had made in a whole fishing expedition; hence rickets and beri-beri had been common. Matters were now in this respect very much improved. He mentioned also that the whale had proved a wealthy source of pituitary gland for the purpose of making medical extracts, and he had been instrumental in supplying a great deal of this material to Dr. Harvey Cushing and others. Whale was good eating, and especially the "small" muscles of the eye, which provided a joint the size of an average beefsteak.

"VARENECOSE" ELASTIC HOSIERY.

WE have received from Le Brasseur Surgical Manufacturing Co., Ltd., of London, Birmingham, and Paris, a sample of an elastic stocking which is constructed of a finely woven but resilient fabric giving firm support. The stocking has a good appearance and the material suggests durability,

A SERVICE OF HEALING.

A medical correspondent writes:—For three days of last week a Mission of Healing was held in the Parish Church of Frizinghall, a suburb of Bradford. The third day—on which I was present—found the church nearly full half an hour before the service began. People were being carried in on stretchers, others pushed in on bath-chairs, others helped in with one, two, or three attendants; only those with tickets applied for beforehand were admitted in the first place, though others came pleading to be admitted, and I fancy these were allowed in when the service began. Throughout the church, while waiting, was quiet and expectancy. Prayers were going up from those assembled, and well-known hymns were being played quietly by the organist. The organisation was good. Police outside the church regulated the traffic, and helped to make it easy for the sick folk to get into the church. Inside, stewards were at hand to show all comers to their seats. Ambulance workers were busy carrying, doctors and nurses were at hand to help the sick in emergency. The people came from different places of worship, many being accompanied by their ministers.

The service was opened with a short explanation from the Vicar of Frizinghall, Rev. J. H. Warner. He told how he had invited Mr. Hickson to come to his church, and what a response he had had to his offer of tickets of admission to the service. The Bishop of Bradford, Dr. Perowne, who followed, mentioned some instances of benefit received by those who had been present at the service the day before. He then led the congregation in prayer. The Missioner, Mr. J. M. Hickson, then ascended the pulpit. He is a layman of the Church of England, with the appearance of an ordinary robust business man. He has a strong voice, and speaks simply and fluently. His sermon was based on the need for more reality in religion, for more simple belief in Jesus Christ and His promises. He emphasised the fact that those receiving help from the service would only get what they were ready for, what their faith allowed them. He showed that we were weaving our own garments in our lives and actions. He explained at the outset that it was not any power of his that would heal the sick, but all power was from Jesus Christ. He said he had had missions all over the world and mentioned one in India. Mohammedans then came to be healed. He told them that he was acting in the name of Jesus Christ, and asked if they would acknowledge Him. Their answer was that Jesus Christ was called the "Healing Prophet" in their Koran. Mr. Hickson went on to say that it was no good him talking about physical healing only. It was peace in their hearts that folk needed as well as relief from affliction and ease from pain. He believed that everyone would go away at peace in their hearts if they were sincere in their prayers. Finally he said he did not see why any church should not be a healing church, if groups of those who believed it possible would meet and pray for this.

The sermon ended, Mr. Hickson asked that there should be no moving about or talking while the sick came to the altar conducted by the stewards. Mr. Hickson and the Bishop went first to those on stretchers and to those who could not walk. Mr. Hickson laid his hands on them, the Bishop gave the Church's blessing, and the patients were carried or helped out of the church. Women removed their hats and held them in their hands. All going up for blessing carried cards stating a few particulars of their illness. The rest of the congregation sat quietly or prayed; there was no emotional outburst. It was hard to see anything outside the church door on account of the crowd. The majority of patients came out as they went in, except for a look of calm on their faces. The Missioner laid no emphasis on immediate cure, but some cases have been reported. There is to be a service in the church at the end of the month, when report will be given as far as possible of the results of the mission.

SCHOOL DRESS.

In spite of the adverse criticism periodically levelled at the modern woman's dress, it is probable that never before—at least since the simple but becoming fashion of woad went out—has it been as hygienic as at the present day. Although until recently the dress of the child of school age still retained many of the old undesirable features there are welcome signs of an improvement in this direction also. In the borough of Westminster an educational campaign has been carried on for some time by Dr. Octavia Lewin, medical officer to the Greek-street centre. At a weekly "nasal hygiene and special exercise" class a careful examination is made not only of the physical condition of each child, but also of its clothing, notes being made not only of such defects as constricted neck-bands, strings of petticoats, tightness across the chest or under the arms, but also of the character, number, and weight of the garments worn. In the case of boys the special points noted are the collars, the presence of studs pressing on the neck, tight braces and waiscoats, and tight arm-holes. Great emphasis is laid by Dr. Lewin on the necessity for allowing plenty of arm-hole room both for babies and for older children, constriction in this region hampering the respiratory muscles and encouraging stooping. All garments are cut low under the chin so that the neck is left bare above the clavicle. A particularly sensible school dress, a patent for which has been obtained is so cut as to hang perfectly from the shoulders irrespective of adjustment; an adjustable box-pleat with lace fastening allows for growth and enables the garment to fit comfortably for from 18 months to two years. The dress is also adjustable as to length. Another hygienic device is the provision o a breast pocket with a handkerchief attached by a tab to a button sewn inside the pocket. The use of an "individua handkerchief" is rightly urged for even the youngest infants. The new ideas are catching the ear of the mother and the coming generation will certainly benefit.

TREATMENT OF PAINFUL CRAMPS AND MUCOUS COLITIS.

To the Editor of The Lancet.

Sir,—In reply to Dr. E. W. Dewey's inquiry regarding painful muscular cramps in rheumatoid arthritis, I have frequently found that the most effective remedy is validol taken in doses of from 20 to 30 drops at bed-time, an repeated every hour if required. I have also found dimol taken regularly, very useful.

In reply to "M. C.," I have found excellent results in the treatment of mucous colitis from the use of choleo-kinase It is, of course, necessary that special diet on Combe's line should be given; and care should be taken in the giving c aperients; my best results have been with the use o thaolaxin.

I am, Sir, yours faithfully,

Bath, Oct. 18th, 1924. Wm. Armstrong.

To the Editor of The Lancet.

Sir,—May I suggest to "M. C." that he tries the effec of large enemata of normal saline in mucous colitis. Th salt solution, at a temperature of 102° F., should be slowl run in from a douche-can holding two quarts and raise 18 in. above the level of the anus, while the patient i lying either on his face or his back, the former being, think, the more convenient position. The tube shoul just pass the internal sphincter. If there is any pain afte a few ounces of the solution have been given, this is probabl due to a spasm of the intestine, and if the rubber tube b pinched so as to stop the flow for a few minutes the pai will pass off and the injection can be continued till th patient has had as much as he can stand, which will probabl be nearly two quarts. The best time for the treatment which should be given daily, is in the morning, if possibl after the bowels have acted. As any intelligent patien can give himself the injections, the assistance of a nurse i not required. Aperients should be avoided, as they ma counteract the soothing effect of the saline. This metho of giving high enemata was recently described in the *Medic Review* by two American radiologists, who had watche on the screen bismuth injections thus administered pas into the ascending colon.

I am, Sir, yours faithfully,

Llangollen, Oct. 20th, 1924. May Rathbone.

THE "BROWNE" STERILISER CONTROL TUBE.

Effective sterilisation by steam depends both upon th steriliser and the person using it. By the adoption of th "Browne" Steriliser Control Tube (Albert Browne, Ltd Chancery-street, Leicester) the degree of heat which ha penetrated to the innermost parts of the contents may b seen at a glance. The device consists of a small, sto sealed glass tube containing a liquid which is unaltered a 100° C. (212° F.), but which after being subjected to 115 (240° F.) for ten minutes becomes straw coloured. Aft 20 minutes at the same temperature it becomes light brow and after 30 minutes or more a deep brown. Tubes place in a batch of dressings or other material to be sterilised wi indicate by their colour when taken from the sterilis the duration and the intensity of the heat to which th contents have been subjected. The tubes can only be use once.

Stethoscope.—In reply to an inquiry for a place on th Riviera suitable for a case of rheumatoid arthritis (Th Lancet, Sept. 13th, 1924, p. 582), Dr. H. M. Mackenz writes from Santa Margherita Ligure, Italy, to say that th place is sheltered from cold winds, the winter climate pleasant, November being the only rainy month. Patient report that they sleep better, and are more free fro rheumatic pains. The cost of living in an hotel is £3 t £3 10s. per week, including all taxes; a pension might somewhat cheaper. There is pleasant society, not too ga Rooms should be booked in advance, as the hotels ar likely to be full this winter.

An Address

[ABRIDGED]

ON

IDEALISM IN PUBLIC HEALTH.

ieing the Presidential Address delivered before the Annual Meeting of the Society of Medical Officers of Health on Oct. 17th, 1924,

BY ROBERT A. LYSTER, M.D., CH.B., B.SC.,
D.P.H. BIRM.,
UNTY MEDICAL OFFICER FOR HAMPSHIRE; LECTURER IN STATE MEDICINE, ST. BARTHOLOMEW'S HOSPITAL, LONDON.

A RESPECTED member of the Council, and a former resident of this Society, has frequently reminded us iat once upon a time there was an attempt made by ie Society to draft and issue a leaflet describing ie proper way to disinfect a room, but that the tempt had to be abandoned because of the divergent iews that members were found to hold. Of course, is particular attempt may have been made at a ecially difficult time, when views upon the subject in iestion were undergoing considerable change, but ie incident serves to illustrate the fact that upon ethods of detail, and minutiæ of administration, e can quite healthily and properly differ until perience indicates the true solution. At the same me, there ought to be little or no difficulty in setting p standards or ideals upon which we can all agree, en while we may be pursuing different paths towards iem, in the hopes of attainment. If the ideal is tablished and kept in view, then each and everyone ill readily abandon his own particular path if, and hen, he finds that it is not leading towards the desired al.

Because the establishment of definite ideals by this ciety is so clearly desirable I decided to devote my ldress to-day to this subject, and to try to indicate riefly the various subjects which should be crowned ith ideals for our attainment.

Most people will agree that, during recent years, iere has been a definite revival of idealism. Hardly day passes in which we do not read of some form r another of idealism, constituting, as it does, the hief influence at work in almost every sphere of iman activity against the purely materialistic titude of life.

IDEALISM OR CANT.

In establishing and maintaining ideals we must careful to separate them entirely from various ints or obsessions which are so ready to obstruct ogress. One of the worst forms of cant posing as an eal is the claim, usually made by men of assured sition and substantial income, that the best kind professional man cares little or nothing about the oney he makes by the exercise of his profession. his belief is based upon the well-known fact that a ofessional man such as a doctor is often so enthusitic about his work that he will do it supremely well, hether he is to be paid handsomely for it or not. other words, he simply cannot do work with the le idea of making money by it, and is self-compelled do his best apart altogether from the subject of muneration. It is not that he does not want money, it that he cannot allow himself to do his work badly. n the other hand, he is usually just as keen as any adesman in selling his wares at the highest prices, id has at last realised that professional combination id collective bargaining constitute the only method hereby he can command a fair deal. For its own otection the methods and practices at present noted by the term "Trade Unionism" must sooner later be adopted by every profession. During the urse of my remarks I shall have more to say about nting catch-phrases masquerading as ideals. The leged "undermining of parental responsibility" by providing treatment for a weakly child is one of these masqueraders, and among others may be mentioned "the maintenance of the great voluntary principle" which is used as an excuse for handing over large sums of public money without adequate control. Similarly, the obstruction offered to great preventive measures in the alleged "interests of morality" by groups of persons who appear to be the victims of a form of sexual obsession is by no means an uncommon hindrance.

I propose to discuss the subject of idealism in public health under four chief headings—namely: (1) Professional: (*a*) General, (*b*) the P.H. branch. (2) Service ideals. (3) Ideals for our Society. (4) Personal ideals. I am well aware of the fact that these four groups are not at all distinct, being, in fact, inextricably interlaced, but the classification may give some coherence to the discussion of a subject that offers many temptations for digression.

PROFESSIONAL IDEALS.

A. *Training.*

Public health having come into its own to some extent and being recognised generally as a subject of outstanding importance, it is not unreasonable to suggest that the subject of preventive medicine should occupy an adequate proportion of the time of the medical student in training. The General Medical Council said, a few years ago, "That throughout the whole period of study the attention of the students should be directed by his teachers to the importance of the preventive aspect of medicine." One wonders what effect this pious expression of opinion, without the slightest backing in the way of regulations, and without any suggestion on the part of the Medical Council as to how this desirable condition should be brought about, has influenced the courses of instruction in the medical schools. After many years' experience as a member of the teaching staff of the medical schools, and as an examiner, I venture to say that expression of opinion has not up to the present had appreciable effect, and that it is not likely to have much so long as the medical schools continue to be, as they probably always will be, governed almost entirely by clinicians. Clinicians, as a general rule, will rarely be sufficiently interested in prevention to undertake any real teaching of it. In a few special cases clinicians have distinguished themselves by their interest and enthusiasm in prevention, but they are the exception and not the rule. Men who have for years devoted the whole of their attention to the diagnosis and treatment of disease are not likely to take up a fresh hobby and to become enthusiasts in prevention. By the time they become teachers in medical schools their interests have become established, and although they may make exceptionally able teachers in diagnosis and treatment, yet they are not likely to arouse in the average student any interest or enthusiasm for prevention.

If the prevention of disease and an increase in the amount of attention given to the public health is as desirable as seems to be generally admitted, then surely it would be worth while to carry out an experiment in some medical school, and to try to establish there a bias in favour of prevention. At the present time the average medical student leaves his school a fully qualified medical practitioner without any real knowledge of, and without any inclination towards, the study of prevention. This is entirely wrong, and must be altered if we are to make such advances in public health as we all desire to see brought about.

B. *Pay.*

The general question of professional remuneration is undoubtedly a matter which can and should be guarded and controlled by the profession as a whole, and it is gratifying to be able to record that substantial advances have been made recently in the organisation of the profession for mutual defence. Still more satisfactory is the fact that there has been

5279

on the part of the profession generally a gradually increasing realisation that the general subject of professional remuneration is inseparably bound up with the subject of the rate of pay of the public health service. Repeated warnings on this subject some time ago received scant attention, but the idea was driven home recently in an unmistakable fashion when the representatives of the medical profession, during the negotiations with the Ministry of Health concerning the subject of panel practitioners' pay, were confronted with a powerful argument in favour of gross underpayment in the form of a reference to the miserably inadequate salaries for which local authorities have during the past few years been able to secure whole-time medical officers with the consent of the Ministry. After this object-lesson there should be no further difficulty in securing the whole-hearted support of the profession in the reasonable demands now being made by the public health service for an improvement in the scale of remuneration. If we can, in connexion with this subject, bring about a general acceptance of the principle that underpayment of any branch of the medical profession constitutes not merely a danger to the whole profession, but also a danger to the public, then there should be no further difficulty in this matter. Underpayment of the public health service means a dissatisfied service, which is as much a public danger as a neglected epidemic or a hidden plague. It also results in the entrance into the service of men who are incapable of succeeding elsewhere.

The salaries scale drawn up by this Society with the British Medical Association will do a great deal in establishing the ideal of equal pay for equal work. Dr. Barlow, in his presidential address last year, called attention to the glaring anomalies which exist in various parts of the country with regard to remuneration, and very reasonably suggested that we did not deserve the title of a "public health service" until we had remedied matters. There is every reason to believe that our salaries crusade at the present time has made a substantial commencement on those lines, but the system of promotion in the public health service can never be satisfactory unless, and until, a scheme of national medical service is created.

PUBLIC HEALTH SERVICE IDEALS.

A. *Training.*

A matter which is immediately the province of the public health service and this Society is the special post-graduate training for the Diploma in Public Health, and the examinations to which such training leads. In the past the public health service, as represented by the Society, has had an inadequate voice in the determination of the courses of training and the kind of examination for the specialist in public health. Few will be able to contend that such subjects are a matter for a *General* Medical Council, or any small body of men, however able they may be in various other branches of medicine and surgery, who have had little experience, and in many instances no training in public health matters. The time has come when the public health service must insist upon taking a hand in the matters relating to the entrants into its specialty.

There are too many portals of entrance to the public health service, and too many examining bodies granting the Diploma in Public Health. One of the ideals to be established by the service and fought for by this Society should be a reduction in the number of qualifying bodies with a view eventually to establishing one portal. It is true that the new regulations in connexion with the Diploma in Public Health recently issued by the General Medical Council may result in a diminution in the number of bodies offering courses of training for this examination, and possibly in a decrease in the number of examining bodies, but it is the opinion of many experienced members of the public health service that the whole subject needs entire revision.

B. *Conditions of Work.*

1. *Lay Control.*—Perhaps the greatest of all t causes of comparative failure on the part of certa medical officers is the fact that their conditions work are unsatisfactory. It should be laid down an important ideal that the public health departme must control all the medical work of the local auth rity. The medical officer of health should be the r as well as the nominal head of that department, a he should not be subjected to interference or sup vision on the part of any other officer and should d only and directly with the local authority and committees.

2. *Security of Tenure.*—This has long been a still remains one of the ideals of the public heal service. Great were the rejoicings when it was p claimed that security of tenure had been obtain at long last. A later examination of the positi however, showed that what was called security tenure meant merely that the appointment could terminated only with the consent of the Ministry Health, who in its turn proved to be ready in certa cases to agree to reductions of salary without rega ing such changes as a violation of the principle security. The present position is that we have security at all, as a security of office without securi of salary is merely a farce.

3. *Superannuation.*—This is an ideal partia attained. In some areas a fairly satisfactory sche of superannuation is in force, but there are t improvements of the position which we must ma tain as ideals. Those are: (*a*) The adoption of t Superannuation Act should be compulsory all o the country. (*b*) We must insist upon special conc sions for medical officers of health, since no lo government officer requires by law anything l such a long period of training and apprenticeship is required from the medical officer of health.

4. *A Specialist Service.*—Our expectations of continuous improvement in the personnel of t public health service by the gradual replacement the untrained medical officer of health by the special officer have not been realised owing to the weakn of the Ministry of Health in granting their appro to the appointment of men without the D.P. qualification. The Order itself needs revision, b the Society should press for its rigid administrati in the meantime.

5. *Research Work.*—Great possibilities for resea work surround every medical officer of health a every member of his staff, and one of our id should be that this vast field for research should no longer neglected. The average medical officer health is so overworked as to have no time to g to research; opportunities for research should demanded by the service.

Dr. Robertson, in his presidential address, 19 expressed the view that a small committee should appointed to suggest subjects into which research urgently needed, and perhaps also to suggest general lines along which this should be carried I should like to repeat this suggestion. The allocat of public funds for the purpose of research wa brilliant idea on the part of Mr. Lloyd George, it raised hopes in all of us that some organised eff was about to be undertaken. Unfortunately, expectations have not been realised, and so far as public health service is concerned, the establishm of the Medical Research Council has been a gr disappointment. That body appears to have sympathy with, and no desire to coöperate with, public health service, and such attitude is to detriment of the public health. The present pol of concentrating essentially upon purely laborat investigations may lead to success, but I am pers ally convinced that general investigations in coöp tion with medical officers of health would lead m more rapidly to the solution of many of our d culties. Bacteriology has undoubtedly secured m brilliant successes, but it is matter of common kn edge and regret that it has apparently failed up to he present to help us to the extent we anticipated vith regard to many of our common infectious liseases.

Cancer research appears to be fascinated by the ancerous processes and the reactions of the healthy issues to such processes. It is concerned largely vith the surgical aspects of the subject, together vith purely laboratory and microscopical investigations. A study of the recently published statistical nquiry of Dr. M. Hindhede seems to indicate that t the present stage we might learn more from eneral conditions than from purely laboratory nvestigations.

6. *Propaganda.*—We should allow no limit to be set o the sphere of the health officer in this regard. There is no doubt in my mind that the public health ervice is the proper centre for organising and carrying ut schemes of public propaganda, and that the central ody in control should be this Society. No other ody possesses the necessary experience and scientific nowledge without which propaganda work may at ny time become a great and serious danger, and even scandal. Small wonder that Dr. Barlow, in his residential address last year, expressed amazement hat outside bodies are being seriously suggested by nedical men as the proper organisers of propaganda vork in connexion with public health.

C. *Ideals of Local Government.*

1. *Unification.*—Unification of the health service is nother ideal. The Ministry of Health Act, establishing he Ministry, seemed on paper to have secured central nification to a considerable extent, but experience as shown that our sanguine expectations in this irection have not been justified. The separation of he medical work of the Board of Education from the Ministry of Health is just as complete as ever, and any lleged unification in that direction is merely makeelieve. It has long been an established ideal of this ociety that practical unification in this direction is rgently necessary, and I have no doubt that during he coming session the prosecution of this campaign vill be continued.

Local unification of medical services is still a pressing eed. All public medical work should be combined in ne department under one head, and as far as possible ontrolled directly through one committee of the local uthority. Perhaps the most important unification, ery many years overdue, is the absorption by the ublic health authority of the medical work under he Poor-law. For many years the Poor-law has ampered and hindered public health work, both entral and local, to an extent which is by no means ully appreciated by the public.

2. *Areas for Local Government.*—Medical officers f health, as local administrators, have obtained aluable experience in local government, and we hould be in a position to advise the public as to the lterations that are desirable in the structure of local overnment.

The vital problems of local government structure ave remained virtually untouched for 30 years in ountry districts, and for more than 40 years in the owns. Governing bodies have remained unaltered hile the work of the local authorities has developed lmost beyond recognition, and during the same time arious and technical changes have rendered many of e old areas obsolete. The time is overdue for a igorous attempt to fit local government organisation the new opinions and changed conditions of to-day. Any Government which attempts a thorough form of local government is certain to arouse widepread opposition from vested interests; all political arties admit the urgent need for reform and yet all re afraid to tackle it. Pending the reorganisation of cal government areas very great reforms could be rought about by the simplification and cheapening the means of obtaining fresh powers. Private Bill gislation is ridiculously slow and costly and can nly be undertaken by comparatively wealthy areas, and it has been recently suggested that a standing committee of the House of Commons should be empowered, without special legislation in each case, to sanction the granting to local authorities of fresh powers for which precedent already exists. Such a suggestion should receive the active support of this Society.

3. *Voluntary Associations.*—An administrative ideal is that public money should be spent only under the direct control of the local authority. The practice of the Ministry of Health in giving direct grants to local voluntary associations is opposed to the public interest. The result is to encourage the voluntary association to disregard the local authority and to act independently, and in such circumstances a properly coördinated scheme, with adequate care and control of expenditure of public money, becomes impossible. At the present time the Ministry of Health and the Board of Education are paying large sums of public money direct to county nursing associations, district nursing associations, welfare centres, and all kinds of voluntary associations, with results that are deplorable from the economic expenditure of public funds and the point of view of efficiency of organisation.

The strangle-hold of the big voluntary associations upon public health work has become one of the dangers of health work. No one appreciates or values more highly than myself the valuable work accomplished by small local associations for after-care of tuberculous persons and defective school-children, and also by those voluntary workers attached to maternity and infant welfare centres all over the country. These deserve the highest praise and every possible encouragement, but the big associations and "national councils," with whole-time paid officers (a curious kind of "voluntary" work), invariably attempt work which, in my opinion, is far better done by officers employed and controlled directly by local authorities.

The point of view of the unfortunate recipient of the attentions of voluntary associations rarely receives any attention, but the deputation which attended recently upon the Ministry of Health had very definite opinions upon the subject, and pressed for the abolition of the voluntary system in connexion with the welfare of the blind, and the establishment of direct municipal and State control.

Everyone with experience of work amongst poor people knows quite well how bitterly they resent the inquisitorial visits of the average voluntary worker, and how differently they regard the impartial and tactful whole-time officer of the local authority.

The ideal that public administration should be carried on by public officers and not by voluntary associations can only be departed from with grave danger to the State and to the individual. This is specially the case in connexion with the administration of the Mental Deficiency Act. The result of the influence of voluntary associations and voluntary workers has been that the scope of the Act has been strained so as to include within it cases that are not really covered by any definition in the Act. The public as a whole would probably be amazed to know exactly what has been done under the Mental Deficiency Act in this direction, and I feel sure that the public exposure of a few cases would lead immediately to a demand for an expert revision of every case now in an institution. The best "voluntary worker" is the popularly elected representative of the public upon the various local authorities. His services are purely voluntary and every medical officer of health is the expert administrative officer of a body of *genuine* "voluntary workers" who are in their turn responsible to the public. It is a curious mentality which puts a halo round self-appointed members of so-called "voluntary associations" and their (usually unqualified) officers.

D. *Central Control.*

There has been a constantly increasing public danger due to a growing inclination on the part of the central authority to make rules and regulations for all sorts of detailed conditions, and to exercise a supervision over minutiæ of administration which, if successfully established, can only result in a degradation of local government. This pernicious tendency is the cause of an increasing irritation on the part of local government officers and local authorities. It is gratifying to be able to record the fact that recently the Prime Minister, and also the Minister of Health, expressed opinions that the powers of local authorities should be greatly increased, and that there should be greater freedom in local government.

IDEALS FOR THE SOCIETY.

A. *Membership.*

The first of our ideals with regard to the Society should be that it should secure as members every medical man in the employ of local authorities.

B. *Policy.*

During the coming year I hope that we shall begin by enunciating certain policies or ideals and in connexion with each policy commence a campaign in order to achieve progress. The Society should lead the way in public health. It should be one of the policies of this Society to issue from time to time manifestos to the public upon subjects of public health importance. Our influence was recently illustrated in connexion with the notorious milk circular issued by the Ministry of Health which in the opinion of most of our members was against the public interest. A very moderate amount of organisation on the part of the Society resulted in such an outburst of protest that the offending circular was withdrawn.

C. *Publicity.*

I have felt for some time that it is necessary for the Society to make itself more articulate. It must cultivate a public voice, not merely a professional technical voice through our journal, and must organise means whereby the public ear can be secured.

D. *The Protection of the Public.*

Another of our ideals for the Society of Medical Officers of Health should be the protection of the public from the extremist, whether the extremist be the alleged economist at one end of the scale, or the faddist who wants public money spent on all kinds of fantastic and hare-brained schemes at the other. It is heart-breaking to read the remarks recently made by an eminent medical man, to the effect that if the raising of the standard for the D.P.H. examinations should continue to result in an insufficient number of medical men entering the service on account of the inadequate salaries paid therein, then it might be necessary to reduce the standard of the examination in order to increase the supply. We do not believe that the public would allow such a betrayal of their interests.

As an illustration of the fact that the ideal solution often lies between the proposals of the extremists we may point to the opposing theories propounded by the extreme eugenists on the one side, and the sanitarians (as we might call them) on the other. The extreme eugenist is supposed to believe in selection and the elimination of the unfit as the essential means for racial improvement, while the extreme sanitarian has alternative "panaceas" in the form of sunlight, housing, welfare centres, and such like. Both these opposing bodies are right, and both are wrong. The scientific and thorough application of the eugenist principle is unthinkable in the present state of civilisation, but the necessary scientific principles which underlie the control of racial developments are perfectly sound, and will have to be followed sooner or later if the race is to be saved from unnecessary deterioration. The sanitarian's proposals must be applied to existing individuals, and the application of their methods will undoubtedly result in improvements. Without eugenic methods, however, there is grave reason to fear that the increase of insanity, the numbers a prolificacy of the feeble-minded, the survival of weakly, and multiplication at the wrong end, overload the race, and will drag it downwards.

The solution seems to be the adoption of b principles—i.e., the development of all members the community by means of careful control protection of the circumstances of life genera accompanied by a sane and scientific elimination of unfit of the future. We are trying at the present ti to carry out this in a costly and stupid way. institutions for the mentally defective are o crowded and local authorities all over the country being urged to spend immense sums in building m Large numbers of unfortunate people will be demned to lifelong imprisonment in these instituti and will never know the blessings of a free ordinary existence, or of ordinary family life. often hears it said that lifelong imprisonment is a more serious punishment than a sentence of de and yet there are fanatics, at present in control of situation, who insist upon these unfortunate pe being subjected to this life sentence instead of carr out the very simple process of sterilisation, w would enable a considerable proportion of t people to lead more or less ordinary lives, at littl no cost to the community.

INDIVIDUAL IDEALS.

Unless, as individuals, we concentrate on essential ideal of the prevention of disease, we must fail. We must be ready to sacrifice personal prejudices in favour of the crusade aga disease. At any time we should be willing to sacr our own advancement and advantage for the be of the service as a whole.

Our constant fear should be lest our met become stereotyped and our minds inelastic. Per the greatest danger of all is that our individual vi on religion and politics, which in most instances grown up with us, and have become part of should govern our public health views and bias work in preventive medicine. The elucidation such problems as the prevention of venereal disea simple if stripped of the prejudices which surro them. Similarly such thorny subjects as birth-con and mental deficiency lose many of their difficu if the subjects are considered from the point of of the improvement of the race. If we can esta a supreme ideal—i.e., the public health and prevention of disease—and turn away from o ideals which we may have followed for many ye then many of our present difficulties would disapp

Testing Results.

Among our personal ideals we must place attainment of scientific accuracy, coupled wit determination not to accept easily-tested statem without careful verification. Fallacies should alw be exposed, even if they are popular, wit hesitation.

Leading Public Opinion.

So much has the general policy of the So of Medical Officers of Health been hampered hindered by members whose views upon the su of public health, and particularly concerning prevention of disease are modified by outside siderations, such as political or religious views, with regard to sexual questions, &c., that at present time the Society, instead of leading p opinion, is actually lagging behind it in many resp While our wheels are being clogged by the preju of the prejudiced few, people outside the profe are overtaking us, and will soon be in advan our opinions as a Society.

Sex Mania.

One of the most insidious obstructions to w public health advancement is liable is due to a of persons who are obsessed with the idea of These people view everything through a kin sexual vision and offer opposition to the scientific prevention of venereal diseases because they fear that as soon as the public are fully aware of the fact that venereal diseases are easily prevented, they will immediately indulge in an orgy of immorality. These same people have recently discovered an argument against sterilisation of mentally defective persons as opposed to perpetual imprisonment, their suggestion being that mental defectives thus treated and allowed their freedom might indulge in sexuality on account of the removal of fear of the consequences. This sex mania breaks out in various ways. Recently it has taken the direction of an attack upon the healthy and hygienic mode of dress of the modern girl.

Encouraging Results.

We should derive considerable encouragement from the experience of our past ventures which have had even greater effect than we anticipated when they were being planned. For instance, the big reduction in infant mortality that has recently taken place is, in my opinion, due essentially to the entrance of the medical officer into the schools. This, instead of decreasing parental responsibility, set up an entirely new health ideal, which soon had a profound effect in increasing both parental and public responsibility, resulting in a rapid fall in infant mortality. Talk of interference with, or lowering parental responsibility in connexion with help given to poor people in order that they and their children may be kept healthy should not be tolerated by medical officers of health. It might just as reasonably be urged that the provision of first-class roads at the public expense has lowered the moral tone of the motorists, or that free education had weakened the national backbone.

Let us take courage. We are fighting against great forces of evil which threaten to damage or destroy the human race, but we are winning, and we know that we should be winning at a much greater rate if we concentrated on progress and disregarded those clutching hands which seek on all sides to hinder our progress. If we keep our ideals before us, we shall be like Christian, who "went on his way" while "Mistrust and Timorous ran down the hill." Individually, as medical men in the service of the State, and collectively as this Society, let us say with Christian, "I must venture . . . . I will yet go forward."

THE
TREATMENT OF MENTAL DISORDER ON A VOLUNTARY BASIS.

By EDWARD MAPOTHER, M.D., M.R.C.P. LOND., F.R.C.S. ENG.,

MEDICAL SUPERINTENDENT, MAUDSLEY HOSPITAL.

Separate Treatment of Curable Willing Patients.

IN this article I wish to express my personal views as to the advantages and limitations of treatment of mental disorder on a completely voluntary basis entirely apart from certified cases, and to discuss the types of case suitable for this as well as those which actually present themselves. These views are based upon an experience extending over 15 years at mental hospitals of the County of London, nearly three years' work in hospitals treating neuroses and psychoses arising from the war, study of the methods obtaining at six of the chief continental clinics, and the results of 18 months' observation as medical superintendent of the Maudsley Hospital (since its reopening on Jan. 31st, 1922).

The Maudsley Conditions.

This article is intended to be supplementary to my first annual report which was recently published.[1] This report was confined in the main to a statement of fact, all opinion being excluded that might be controversial or have a bearing on possible legislation. I must emphasise that I alone am responsible for the views now expressed.

To render the present communication intelligible apart from the report it is necessary that I should here repeat the statements which the latter contained as to (*a*) the conditions of admission, retention, and discharge; (*b*) the purposes of the hospital. (*a*) The hospital is devoted entirely to treatment on a voluntary basis. Every patient is required before admission to sign a form of application which clearly intimates his right to leave the hospital within 24 hours of giving notice of desire to do so. No patient is admitted under certificate or is certified in the hospital either for retention there or for transfer to a mental hospital elsewhere. I shall hereafter refer to these as the "Maudsley conditions," and the hospitals where they might obtain as "voluntary clinics." (*b*) The purposes of the hospital are four—viz., research, teaching, provision of facilities for diagnosis, and curative treatment.

Opinion may differ as to the relative importance of these purposes, but I shall for the most part confine myself to the relation of the "Maudsley conditions" to one object—viz., treatment of patients solely with a view to cure. This relation seems likely to be the one of most general interest. It appears to me as desirable that research and teaching should be concentrated as that separate treatment of voluntary cases should be widespread. In fact, this concentration is almost inevitable for many reasons, including cost. Briefly, however, it may be said that the "Maudsley conditions" are not detrimental to the functions of research and teaching. In fact, the hospital provides a wider range of clinical material than almost any hospital in the country. The attendance at the out-patient department includes many examples of every type of psychosis and neurosis, and numerous forms of organic nervous disease. It is not possible to admit to the wards all cases of any type, but it is possible to treat there some cases of every type as long as is desirable. Any clinic undertaking only brief treatment of patients suffering from psychoses (even though these included some detained against their will) would have to eke out its resources with those of a mental hospital for chronic cases in order to be representative. In this direction the Maudsley Hospital is, of course, fortunate in being able to draw upon the enormous resources of the L.C.C. hospitals. What cannot be obtained from elsewhere as clinical material are cases at the other end of the scale of severity. I am sure the exclusion of certified cases is at present essential in England to the acceptance of admission by both organic and functional patients whose mental symptoms are really slight. Such cases being the most interesting and valuable for research, and the most instructive for teaching, it is essential to provide a system that will attract them. The possibility of demonstrating voluntary cases is merely a question of tact.

Classification and the Criteria of Admission.

From the standpoint of their attitude towards treatment patients fall into three groups: willing, unwilling, and incapable of expressing an opinion. By distinguishing those of hopeful and unfavourable prognosis six sub-groups may be recognised. There is now fairly general agreement that the opportunity of treatment on a voluntary basis for mental disorders should be extended to those incapable of paying for it in a private institution. Such opportunity, of course, existed in no institution provided out of public funds before the opening of the Maudsley. There is, however, much less agreement as to the view that the public provision for any of the above six sub-groups should be in separate institutions.

I wish to uphold the view that the aim should be to promote treatment apart from the certified of every possible willing case—at least every hopeful one—and further to discuss the limits of this possibility. It is possible that at some future date it may be thought an anachronism to compel those who are willing to accept an asylum (in its original sense) on account of chronic mental disorder to associate with those detained against their will on account of anti-social tendencies. If separation were possible, I believe it would greatly reduce the present discontent among patients and their relatives, which spreads from those resenting detention to those willing to remain, and I believe a surprising number would be found to belong to the latter class. So much is done, however, in the modern mental hospitals with parole, villas, &c., to mitigate the association of chronic willing patients and of the anti-social type, that it is mainly a question of feelings. I am aware of great practical difficulties in altering the present position. There is also an arguable case for the treatment apart from the chronic insane of even the "unwilling" recent cases, say for a year.

---

[1] See THE LANCET, Oct. 11th, p. 761.

Ignoring for the present the cases of the willing chronic, of the unwilling acute, and of the "non-volitional" cases, whether acute or chronic, confining oneself to possibilities of the near future, willingness and likelihood of recovery *from the attack* should be the sole criteria for admission to a voluntary clinic, and neither "earliness" nor mildness of symptoms. In considering mental disorders and their treatment there is apt to be a considerable confusion between the terms early, recoverable, mild, and willing, and a tendency to assume that these are interchangeable, which is far from being the truth. I see no reason why separate voluntary treatment should be confined to "first attack cases." Numerous patients have been treated at the Maudsley who had had several previous attacks—even when some of the attacks had necessitated certification. Repeated admission of suitable cases to the clinic should be allowed here as abroad. I think no attempt should be made to lay down or enforce any legal rules as to the severity or type of mental symptoms which it is permissible to treat on a voluntary footing, provided always that the treatment required must be forthcoming—e.g., adequate supervision of those who might at times be dangerous to themselves or others. Certainty as to adequate treatment as well as real willingness of the patient require that authority to treat patients on the voluntary basis be only granted in such a manner as to admit of really satisfactory supervision by an external and expert authority. The danger of abuse in these matters would probably, however, be much less in a voluntary clinic under a public authority than in homes or small institutions run for private profit, whatever their rival merits in other respects.

The question of what type of symptoms will often be found to render it inexpedient to retain a given patient in a voluntary clinic is, of course, an entirely separate one from a legal limit. This question will be discussed later.

Advantages of Separate Treatment of Voluntary Cases of All Degrees of Severity.

(1) Much stress has been laid on the stigma associated with certification. I take leave to doubt that this will be much decreased by admission as a voluntary boarder or a non-volitional case to one of those mental hospitals whose names are household words. Especially would this be the case if these patients were treated with the involuntary inmates, and liable to be certified and transferred to that class in the same institution. The chief difference would seem to be in the patient's own feelings, and perhaps in some of those grosser disabilities (such as dissolution of partnership) apt to follow certification. On the other hand, there is no doubt that admission to an exclusively voluntary clinic would be distinguished by the public here, as it is abroad, from admission to a mental hospital.

(2) If it is desired to get cases early for treatment it must be recognised that the great majority of the public will not go or send their relatives to the ordinary mental hospital till this is unavoidable. This is, in part, a question of utterly unfair disrepute, in part of facts. Nobody is more aware than I of the absurdity of the charges made against the treatment in the mental hospitals, particularly those of the County of London with which I am familiar. Nobody could possibly have a higher respect for their work including its medical aspect. In my report I deprecated all comparison between the results of the Maudsley and the mental hospitals, because such a comparison is utterly unfair to the latter institutions. But there is a difference of attitude on the part of the public which is impossible to ignore, and which is brought home daily to those who have worked at both types of hospital. It is not possible entirely to abolish this distinction by patience and propaganda because it is not altogether unreasonable, depending as it does, on the indisputable fact that for some of their patients the mental hospitals are places of detention rather than treatment.

(3) It is possible to give a much higher degree of liberty in a hospital where all patients are voluntary and selected. This liberty is one of the chief requirements to attract patients. But even when restrictions are necessary they are much more cheerfully borne when there is an alternative to submission. Progressive restoration of liberty and responsibility outside as well as in the hospital is a most important feature of treatment, especially of the "neuroses," and is hardly practicable in a mental hospital.

(4) The institution of separate voluntary hospitals for hopeful cases seems to me the only chance of providing, for all such, suitable personnel in the numbers required according to modern ideas. There is undeniable difficulty in filling the insufficient present number of medical posts at the mental hospitals with energetic and efficient men interested in their profession. Exactly the same difficulty exists abroad, and it is inherent in the nature of the work. On the other hand, there is no difficulty on the continent in obtaining the large staff needed in the psychiatric clinics, especially when these are also neurological. I believe it will prove possible also to get a much better type of nursing staff for voluntary clinics.

The best evidence in favour of complete separation of voluntary cases consists in a difference of general atmosphere obvious to everyone working in a hospital admitting such cases only, and familiar with other hospitals where some patients are compulsorily detained. Coupled with the absence of the monotonous daily demands for discharge, which are so depressing to fellow patients as well as the doctors, one notes a greater degree of cheerfulness, contentment at least with the conditions of the hospital even if the patients are unhappy about other matters, and almost total absence of quarrelling with fellow patients. Patients are far more tractable, and breaches of hospital rules of any kind very rare. The attitude to both medical and nursing staff is quite different. An expression of gratitude on discharge by patients and relatives, whether in words or by letter, is practically universal. A large proportion of those discharged subsequently attend regularly in the out-patient department. Where this is unnecessary, many come back at intervals to see nurses and fellow patients in the wards, and this is encouraged. Requests for readmission are numerous from those who have had to be discharged owing to improbability of further material improvement, from those who have relapsed after improvement, and from those who have discharged themselves contrary to advice. The last type of such request has occurred several times within a few days of discharge ; it is acceded to where possible. All these differences depend upon the type of case under treatment as well as upon the treatment provided, and the system acts by selection as well as directly. But at least it may be said that it reduces the disagreeable aspects of treatment for those selected, and is therefore presumably conducive to recovery.

Respective Provinces of the Voluntary Clinic and Present Mental Hospitals.

Even were there a provision of such hospitals as the Maudsley for all willing cases of recoverable mental disorder, they would only be a supplement and not a substitute for the ordinary mental hospital. Experience shows that there are very numerous eminently recoverable cases that cannot be treated at a voluntary clinic—e.g., many cases of acute mania and acute confusional states—either because the patient will not consent to admission, or will not remain until discharge is safe, or is intolerably disturbing to other voluntary cases. There can be no doubt of the desirability of the extension to the ordinary county mental hospitals of the power to receive voluntary cases; many who have recovered from an attack will doubtless return there by preference in event of relapse. I think the power of receipt of "non-volitional" cases (with the right of discharge on request) would be chiefly useful in the ordinary mental hospitals for reasons discussed below. Neither of these arrangements, however, will in any way diminish the need for such hospitals as the Maudsley intended *solely* for voluntary cases. An extensive previous knowledge of the types admitted to an ordinary county mental hospital and comparison of these with cases treated at the Maudsley leaves no doubt in the mind of my colleagues and myself that a very large proportion of patients now certified could be treated in such clinics until it was clear whether recovery were possible, and in favourable cases until recovery.

Certain Objections to the Maudsley Conditions Examined.

Almost every conceivable criticism has been directed against this system in an entirely friendly spirit. The fact that many of the criticisms are mutually contradictory leaves it still possible that some are sound. In fact, there is some force in most of the arguments, but modification made according to the suggestions received would have disadvantages out of proportion. There is no one of the rules to which exception would not occasionally be desirable, but rules are necessary and hard cases make bad law. The acceptance of all the objections and suggested alterations discussed below would leave the Maudsley indistinguishable from the ordinary registered mental hospital. At the end of 18 months I am obstinately convinced that the great balance of advantage for the purposes of the hospital rests with rigid adherence to the policy of maximum liberty deliberately adopted. Among my colleagues there have been some familiar with the conditions of registered hospitals and of mental hospitals of this country, and of numerous clinics of the continent and America. I am not aware that one has held that the balance of advantage would rest with the reversal of any item of the policy adopted at the Maudsley.

(1) It was prophesied by some that it would prove impossible to fill the hospital. The figures for the first year's working are a sufficient answer. 1012 cases were treated, including 894 as out-patients and 452 as in-patients, and there was probably a nearly equal number of those applying by letter who were rejected as ineligible without interview. Fullness depends, of course, solely on stringency of selection for admission and readiness of discharge. Undoubtedly there is less pressure on male wards for neurotics, because they cannot afford to leave employment.

(2) It was said on the one hand that admissions would consist entirely of undesirable neurotics of whom it would be difficult to get rid, and, on the other hand, that it would prove impossible to treat neuroses and psychoses in the same hospital since those with milder symptoms would absolutely object to contact with others whom they would consider insane. The truth in these matters appears to be this. Here, as wherever voluntary patients are treated, *some* are of a dependent type loth to leave their refuge, but by no means all. There is no resemblance in this matter to the situation in hospitals for war neuroses and particularly those for pensioners. That cases of varying severity are incompatible is a fallacy, provided a fair chance is given for classification. The conditions of the acuter wards are not resented by those needing them. Many contentedly convalescing in acute wards to which they have been admitted will demand discharge rather than accept transfer to a quiet ward. There is little more difficulty about transfer in the opposite direction if all semblance of its use as a disciplinary measure is avoided. In view of the frequency of acute developments in cases where it is impossible to forecast these, to abolish treatment of severe cases would stultify the work of the hospital. The sympathy and tolerance which the less deranged show for those who are more so are remarkable. Practically the only intolerable characteristic is persistent noisiness, which will be further discussed later.

(3) *Admission of severe cases under certificate has been urged on three chief grounds:* (*a*) It would render the hospital more representative for teaching and research; this has been discussed. (*b*) It would render the Maudsley Hospital more useful as an auxiliary to the mental hospitals of the county by facilitating treatment of special cases from these. This would be an excellent object if it were not incompatible with the Maudsley doing its own work. In a majority of suitable cases the difficulty can be simply overcome by discharge from certificate, and this has been done in certain cases. (*c*) It would render possible treatment of some most hopeful cases: those of acute psychoses, where the patient is definitely unwilling. The arguments used below in connexion with the question of admitting non-volitional cases largely cover this point.

(4) *Retention under certificate of certain cases that give notice* has been advocated on the ground of experience in registered hospitals, showing that some voluntary borders are very unsettled till the decision to go or stay is taken out of their hands and then they rapidly improve. These may be balanced to some extent by anxiety cases aggravated by the fear of certification.

(5) *Certification at the Maudsley* of those cases needing transfer to a mental hospital has been thought desirable on the ground that it is the duty of the medical officer who has had the patient under observation to accept the responsibility. Personally, I think it would be an infringement of the spirit of the undertaking upon which a voluntary boarder is received. If a patient is to be certified for transfer it matters little to him who performs the act, but if it be at all practicable I think he should be sent elsewhere for examination by a doctor who may decide against the need for certification. During the tenure of the Maudsley Hospital by the Ministry of Pensions patients were certified for direct transfer to a county mental hospital by the medical officer in charge of the ward and myself as medical superintendent. It was perfectly clear that my visits to certain wards gave rise to uneasy wonder as to whose turn had come now, and any interview which I had with a patient was apt to be a source of terror. I do not believe it would be a material improvement to introduce outside practitioners to certify for transfer, as they would soon become known.

The Question of Admitting the "Non-Volitional" Patient to Voluntary Clinics.

It has been truly emphasised that exclusion of the certified prevents admission, at any rate for the present, not only of the unwilling but of the patients that are too confused to express an opinion either way, and that the latter class includes many of the most hopeful cases. It was decided at the Maudsley Hospital to accept this limitation and to await the passage of a Bill rendering possible the admission of such cases without certification (though subject to adequate safeguards before reception, and to the proviso that the patient would have the same right as a voluntary boarder to discharge within a specified time of his giving notice of desire for this). I should not regard admission under such conditions as any infringement of the voluntary principle, but I am much more doubtful than a year ago how far the legalisation of such admissions would benefit the Maudsley Hospital. I am fairly sure that it would not be of much advantage without considerable additions to both staff and structure. It is now clear that the total number of acute cases that can be obtained under the purely voluntary system is greater than the staff can manage. The problem, e.g., with many cases of mania is not to obtain consent for admission, but to get them to remain until discharge is safe, and this would probably arise with many of the confusional cases. It *might* prove possible without increase in the total number of severe cases to substitute non-volitional patients of better prognosis for some of the psychotics obtainable under entirely voluntary arrangements. But this would require very careful selection of cases, and if the change involved any decrease in power of personal selection by the staff of the hospital it would probably be detrimental and merely lead to a larger number of cases passing through the wards en route to the county mental hospitals. It is necessary to limit the number of noisy cases; persistent noisiness rapidly arouses protests (especially among those to whom the particular patient is unknown) and it raises the problem of getting rid of the noisy patient or losing several others. Moreover, those living in houses near the hospital object. When the accommodation for voluntary curable cases is increased, the reception of more acute cases, including non-volitional ones, will be very desirable if special sound-proof buildings can be provided, and almost impracticable without this provision. The coördination of the work of the voluntary clinics and of the mental hospitals would be greatly helped by the establishment (under the same authority controlling these) of receiving wards, replacing the present observation wards of the workhouses. Expert selection of cases for the two types of institution would then be possible, and patients could be returned for disposal if they became unsuitable for the clinics or unwilling while still requiring treatment. But if the voluntary character is to be maintained the access to the clinics for the majority of cases should be direct, through its own out-patient department, as at the Maudsley Hospital.

Cases Suitable for Treatment.

To me it is almost a truism not only that such hospitals as the Maudsley should exist, but that every hopeful case desiring treatment for mental disturbances is entitled to such opportunities of treatment, apart from those *detained* on account of such disorders. Suitable accommodation should be available to allow of this for every type of such cases, even though the cost per patient for such separate treatment should approximate to that for acute bodily illness (as it does at the Maudsley). But this will remain an ideal until the number of those willing to work and to pay for real improvement begins to approach that of the people who merely enjoy having their blood curdled with tales of imaginary horrors. Into the practical question of eligibility for treatment at the Maudsley three main considerations enter: (*a*) Prognosis; (*b*) the presence or absence of certain practically important features; (*c*) scientific interest. Each of these is a complex question; in practice they are inextricably connected. They are stated in order of importance, but here the last will be ignored, and the second discussed, before entering upon a necessarily brief essay regarding indications of prognosis.

Special Features Influencing Eligibility.

One possible primary division of mental cases is into those *with* and those *without* well-defined physical causes and symptoms. Such a division is, of course, largely artificial. One believes all mental disorders to have an organic basis, and, on the other hand, even where obviously physical factors are present, causes belonging to the three other groups mentioned below may even preponderate. Cases with organic disease, however, are especially eligible for three reasons: (1) Scientific interest, especially for investigation with a view to detection of changes that in lesser degree may at least contribute to determination of "functional" psychoses and neuroses. (2) Promotion of the hospital rather than the asylum atmosphere. Most similar institutions abroad are the university clinic in neurology as well as psychiatry At the Maudsley Hospital many cases of organic nervous diseases are admitted where mental symptoms are minimal or of bad prognosis. (3) Good prognosis in a large proportion of cases. The mental prospects of course, are usually proportionate to the curability of the physical disease, but this is by no means uniformly so. Mental recovery often only requires the establishment of some conditional or even temporary compensation, as in diabetes and Bright's disease, valvular disease, and arterio-sclerosis. In the latter recovery is common from a state simulating advanced dementia. Disregarding the frequency of general paralysis, causal organic disease plays a much larger part at the Maudsley than in an ordinary mental hospital, and is of much greater variety This is one of the features giving special value to clinical work here. An example is hyperthyroidism Though the term was confined to well-defined cases showing marked enlargement, with such symptoms as tremor, tachycardia, and vasomotor abnormalities there were 24 such cases among the first 1000 patients This is a much larger proportion than would be seen at an ordinary mental hospital, the explanation being that while a neurosis is almost constant in hyperthyroidism it only rarely leads to a psychosis. It is an interesting fact that of 24 cases of neurosyphilis in the same first 1000 patients, there was not one of the interstitial variety nor one in which antisyphilitic treatment did material good. Cases of the interstitial type are uncommon in mental hospitals but not so rare as this would suggest, and it might be expected that more would be seen here. Probably the explanation is that early signs are usually clearly physical, leading to attendance at a hospital for organic nervous disease, and that when mental symptoms occur they are most often of a kind unlikely to lead to application here, commonly deterioration of a sort apt to be mistaken for the dementing type of G.P.I. In the first 1000 cases there were 1 illustrating sequelæ of epidemic encephalitis; the proportion has increased lately.

"*Psychoses*" *and* "*Neuroses.*"—To me these terms denote two degrees of mental disorder that usually in the poor are respectively treated under certificate and not treated at all. If this is not the distinction they seem to be mere pseudo-scientific euphemisms corresponding to the more popular absurdity, "It is not mental, it's only the nerves." The difference proves often to be a temporary one; that it is more seems to be most strongly held by those whose experience for practical reasons is mainly limited to one or other type. I am not entirely unfamiliar with more elaborate distinctions, but perhaps my crude simplicity may resemble that of the child unable to see the king's new clothes. It is common and useful in practice to assure neurotics that such patients do not become insane; unfortunately it is not true I think no one with a year's clinical experience at the Maudsley would be disposed to deny the transition from typical neurosis to typical psychosis, either in a series of different cases or in the same case at different times. Maintenance of the reality of the traditional distinction between neuroses and psychoses is merely pandering to the popular tendency to regard insanity as something horrible and different from all other disease. Every effort is needed to break down the barrier. The possibility of joint treatment in voluntary clinics of neuroses and psychoses has been discussed it is not necessary to discuss its advisability because it is inevitable and in force in numerous continental and American clinics. At the Maudsley two-thirds of the beds are in wards suitable for treatment of "neuroses," but owing to the longer average treatment of such, only two-fifths of the first 1000 cases were "neuroses."

Particular Symptoms and Syndromes.—The relation of these to eligibility apart from prognosis cannot be extensively discussed. Cases of mania, though eminently recoverable, are disappointing on account of the frequency with which they give premature notice. They are almost the only favourable type with whom this is common. Noisiness rendering them unsuitable on account of fellow patients and neighbours has been discussed. Obscenity and extreme degrees of violence may require discharge where, as at the Maudsley, even the male acute ward is partly staffed by women. But, so true is it that male cases are often better nursed by women, that I think few desirable patients would need rejection or discharge if the ordinary staff were wholly female with a reserve of male nurses merely for special duties and emergencies. Paranoid cases, on account of disposition to include the hospital in their persecutory scheme, are usually undesirable. Suicidal tendency, in my opinion, should not be considered a bar to voluntary treatment, provided the patient will accept the measures necessary for his treatment. The "safety first treatment" of melancholia is responsible for not a few chronic cases and perhaps some suicides. It is time to face the inevitable reward of taking reasonable risks.

Indications for Prognosis.

Under this heading I propose merely to suggest considerations as to probable recovery from the attack of mental disorder which should at a preliminary interview influence one's decision regarding admission to a voluntary clinic.

(*a*) *Ætiology: General Principles.*—In every case of mental disorder four sets of causes are operative: (1) The innate structure of the whole organism; (2) the changes in it which normally or commonly occur at various ages or such physiological epochs as the events of sexual life; (3) changes induced and dispositions left as the correlates of mental experiences; (4) changes resulting from influences of a purely physical kind. Among the "functional" cases it is futile to try to discriminate groups due to one or even two of the first three factors. All three so interact in every case as to render useless attempts to separate such groups—e.g., Kraepelin's "paranoia."

(1) *Innate or early constitutional tendency* may be indicated by (*a*) family history, (*b*) very early anomalies, either intellectual or temperamental. Neither of these has much bearing on prognosis of recovery from the attack. (*a*) In no form of mental disease is heredity more pronounced than in the manic-depressive type. (*b*) Recovery is common from the psychoses of all forms often superimposed on amentia and constitutional psychopathic tendencies of every kind and degree. If the latter do not per se disqualify for social usefulness, they do not disqualify for treatment of the psychosis in a voluntary clinic. Particularly, of course, is this so when temperamental anomalies are themselves intermittent.

(2) *Association with particular ages and phases of life.*—Practically all extensive statistics bearing on this are vitiated by the fact that only certifiable cases—e.g., in adolescence—have been considered. The question of "dementia præcox" is discussed below. Recurrences in the elderly are, of course, quite hopeful; even first attacks are so, if not associated with dementia. The only other point of note in this connexion is the good outlook in cases *really* dating from pregnancy or childbirth.

(3) *Association with a recent external stress* is the first important single indication for prognosis in functional as in organic disease. There are, of course, various fallacies regarding the relation of the "stress" and the symptoms which cannot be detailed here. The adequate forms of stress correspond in number and relative frequency to the situations which give rise to intense unpleasant emotion in a human being.

(*b*) *Time Relations of the Disorder* are the second important indication. Recency and suddenness of onset of the present attack or a history of previous ones like it *really* followed by recovery are among the points rendering a case most eligible. But these points are so connected with the ætiology and form, that though these time relations are the most valuable index, their significance cannot be fully discussed here and no figures can be given.

(*c*) *Form of the Symptoms.*—This is the last and the most misleading indication for prognosis. Assessment of their value requires prolonged experience and a profound distrust of text-books. Given these one may at least appreciate one's ignorance. To my mind, the various subdivisions of the "functional" group of psychoses are merely syndromes whose names are descriptive terms for a somewhat ill-defined group of mental symptoms present at the moment. I do not believe that any one of them is likely to be more than that, or that the cases of any one group have a constant single cause, either physical or psychical, though presumably each group has *something* specific in its morbid anatomy of a kind which cannot yet be demonstrated. The tendency for investigation to end in the application of some name, and in satisfaction with a merely statistical prognosis based on that name, is a dreadful example of the power of words to stereotype thought. The course of disease depends upon cause, and it is therefore neither to be expected nor is it found that course is parallel to the clinical picture when first seen. The degree to which this is the case has been greatly exaggerated, and any correspondence depends largely upon a process of "waiting and seeing," followed by argument in a circle. For example, I believe the traditional prognosis of "dementia præcox" is largely arrived at by abstaining from applying the name except to cases which duration, &c., have already shown to be hopeless.

If the symptoms constituting *dementia præcox* were defined, and the name *schizophrenia* as a descriptive term without implied prognosis were conscientiously applied to every case showing those symptoms, then I think the prognosis would be found to be very different. I believe this to be borne out by results seen here in what one might term "acute dementia præcox" (of every sub-type), and that it is of great importance in regulating admissions. The schizophrenic mode of reaction depends largely on the age of the patient, regardless of cause, and so has no constant prognosis.

If one uses the term *paranoid states* to include all cases resembling Kraepelin's paranoia and paraphrenia (regardless of minor symptomatic differences—e.g., presence or absence of hallucinations and preponderance of internal or external factors in causation), then a proportion of such cases will be found to recover or to remit and recur in the manner described in text-books as characteristic of manic-depressive psychosis. A proportion will therefore justify admission, but I am not clear how they are to be distinguished by symptoms. Nor does the difference clearly depend on any of the ætiological factors, even could these be fully ascertained before admission, which is often not the case.

The term *manic-depressive psychosis* seems best applied in the sense of Kraepelin's later work to all those states where emotional anomalies are the prominent factors, whether of lifelong duration or occurring in a single attack or in recurrent phases of any form. This type is, of course, relatively favourable as regards the attack. But it merges (through transitional cases in which the misfortunes are ascribed to the faults of self and others respectively in varying ratio) into the paranoid types and so to the prognosis of this.

Under the term neuroses one may include hysteria, neurasthenia, anxiety states, and obsessional states. Their prognosis, of course, varies enormously with ætiology, time relations, previous treatment, and here perhaps especially evidence as to the usual "make up." An important point is the great frequency with which a case quite indistinguishable before admission from a "neurosis," which remains stationary as such, will later show symptoms clearly assigning it to one of the "psychoses," such as dementia præcox, manic-depressive psychosis, or a paranoid state. The distinction with certainty before admission is impossible. Personally, I am increasingly impressed by the difficulty of making anything but a statistical prognosis in all types of functional psychosis or distinguishing except by “ waiting and seeing ” those cases which are going to get well from the attack or permanently. Some tests, whether physical or psychological, on which to base an individual prognosis are a crying need. I think it is one of the great functions of a hospital like the Maudsley, treating all types of case and in touch with all the main mental hospitals of London, to lay the foundations of this. Great importance therefore attaches to efforts now in force to obtain all after-histories by periodical inquiries, and correlate these with symptoms and laboratory tests.

It might be said that the foregoing discussion of indications for individual prognosis in cases of functional mental disorder amount to a confession of ignorance. Constitutional predisposition is negligible, relation to external stress can often only be estimated after admission, form of symptoms is misleading. Recency and suddenness or previous recovery are the best indications, but to deduce the future only after sufficient experience of the past can hardly be called prognosis. A hopeful confession of ignorance is perhaps the beginning of wisdom. I call my view hopeful because it implies that there are hardly any recent “ functional ” cases where the chance of recovery can be excluded, and few that are not worth a trial under the best conditions. Our experience here points two morals, the need of ample similar accommodation and of patience in the most doubtful case. Perhaps the most humiliating kind of experience is the swift recovery at a mental hospital of cases sent there as probably hopeless. Perhaps the most satisfying is the protracted miracle of complete recovery in cases of melancholia—often delusional—kept for many months though seeming to hover on the brink of dementia or death.

FOUR NEOPLASMS OF THE EXTERNAL EAR.

BY MACLEOD YEARSLEY, F.R.C.S. ENG.,
CONSULTING AURAL SURGEON TO THE ST. JAMES'S HOSPITAL AND TO THE LONDON COUNTY COUNCIL, ETC. ;

AND

H. G. BUTTERFIELD, M.D. OXF.,
LATE GRAHAM SCHOLAR IN PATHOLOGY, UNIVERSITY OF LONDON.

THE following four neoplasms of the external ear—three from the auricle and one from the external meatus—are of interest, because two of them demonstrate the insidious way in which malignant disease may begin, while the last to be described shows how easily a mistaken diagnosis may arise in the case of a rare condition.

I.—A. B., 52, a porter, attended at the Royal Ear Hospital in December, 1905. Two months earlier he had noticed a small nodule in the left pinna which “ felt like a shot under the skin.” This growth enlarged and ulcerated after one month. On examination, a hard, raised ulcer, about the size of a sixpence, was found situated in the fossa of the antihelix. No glandular enlargement was discoverable. The whole pinna was removed with the exception of the lobule, flaps being taken from the anterior and posterior surfaces of the concha. Recovery was uneventful. Microscopically the growth (which is now in the Museum of the Royal College of Surgeons of England) proved to be epithelioma.

II.—C. D., 56, medical practitioner, consulted M. Y. in December, 1911. He had noted for eight months the formation of a scab on the superior margin of the fold of the helix of the left auricle. The scabs either fell or were picked off, leaving a raw surface. This surface was about the size of a millet seed, and the tissue immediately beneath and around it was perceptibly thickened. The whole area did not exceed one-eighth of an inch square. The patient volunteered that he was subject to chilblains of the ears, and that he had considered this to be the result of one. He stated that various treatments, including the galvano-cautery, had been tried without benefit. A small wedge-shaped piece to include the growth was removed, and a collodion-wool dressing applied.

The report of the Clinical Research Association wa as follows :—

“ The section of skin shows epithelial processes growin down into the subjacent connective tissue ; in each cas where this occurs it is seen that the basement membrane i lacking at the point of extension. One process is branche and is spreading laterally, associated there are well-marke areas of round-cell inflammation. The condition is to b regarded as one of early malignancy.”

A letter from Dr. C. D., dated Dec. 20th, 1923 says, in reply to inquiries :—

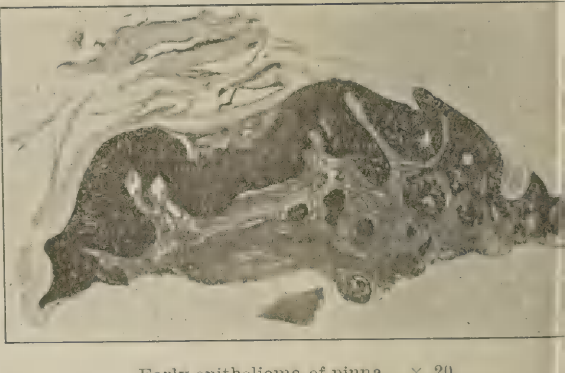
“ I still have my ear intact and no sign whatever of malignant growth. Both ears are ‘ delicate ’ and subject t frost-bites and chilblains in winter.”

III.—E. F., 57, medical practitioner, consulted M. Y. i December, 1923, for a growth apparently similar to that o C. D. It was situated upon the edge of the fold of th helix of the right auricle opposite to “ Darwin's tubercle. It had been noted for a few weeks only, and the chief sympto complained of was pain when lying upon the right ear a night, a discomfort which was sufficient to prevent slee The scab and the abraded surface beneath it was precisel similar to that in C. D.'s case, and at once recalled it to th mind. The growth was similarly removed and a collodio dressing applied. There has been no recurrence after ove six months.

The report of Dr. H. G. Butterfield, who ha also furnished the photomicrograph in Fig. 1, is a follows :—

“ The specimen in this case consisted of a small nodule tissue, roughly lenticular in shape, which measured approx mately four millimetres in its greatest dimensions. Und the microscope the changes seen are all in connexion with th stratified squamous epithelium of the skin, which shows a the central point a deep ulceration and a complete break i the recognisable elements of the normal skin epithelium, an leaves the subjacent cartilage covered merely by connecti tissue, and above that dense amorphous material apparent keratinised. On either side of this deep ulcerated centre t epithelium shows greatly enlarged papillæ of quite irregul outline, and five or six completely detached small islands epithelial cells showing the characteristic layers of sk epithelium. The connective tissue under the epitheliu and in the neighbourhood of the detached islands of ce shows the small round-celled infiltrations characteristic inflammatory reaction. The characters of the specimen as whole, with the ulceration, the irregularly enlarged papil extending into the subcutaneous connective tissue, and t detached islets of cells growing there, point to the conclusi that the condition is an instance of a very early epithelio of the pinna. The accompanying low-power photomic graph (Fig. 1) gives an accurate general idea of the relati ships of the different tissues included in the specimen. It taken from a point away from the centre, since in the para sections it was impossible to get the section flat enough a photograph owing to the presence of tissues of vary consistence, and the specimen was so small that the appli tion of the freezing process would have risked its be spoilt.”

FIG. 1.



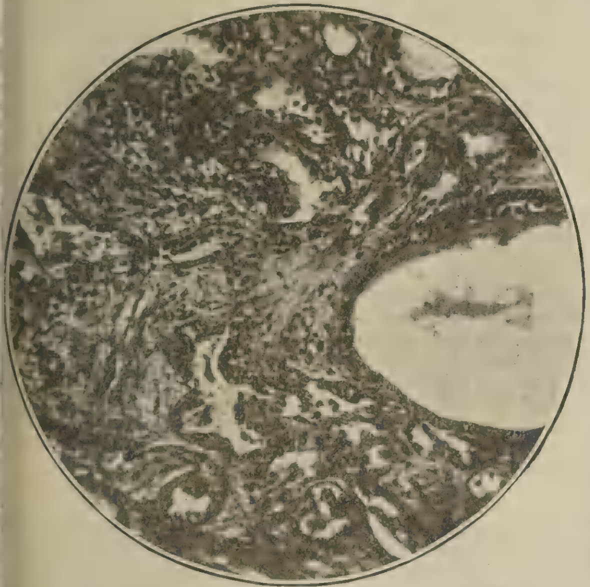
Early epithelioma of pinna. × 20.

The above three cases are characteristic of t very low malignancy of epitheliomata of the exter ear. In our opinion, the malignant growths whi commence apparently at the inner end of the meat and are usually found in connexion with a history of discharge existing for many years, really originate from the tympanum.

IV.—The fourth case is of a different character. It is not only of interest as showing how one can be deceived in the examination of a growth in the meatus, but it is remarkable for its rarity. We have hitherto met with no growth originating in the ceruminous glands.

Miss E. F., aged 45, consulted M. Y. in April, 1919, for gradually increasing deafness in the right ear. She had already consulted a general surgeon, who had informed her that she had a "bony growth" in the passage. On examination, the meatus was found to be occluded by what appeared to be an ivory exostosis. It was smooth, very hard, and apparently immovable when investigated with a probe. As she was averse to operation and there were no symptoms beyond the deafness, inaction was advised. She returned in November, 1923, complaining of increased sense of obstruction, slight occasional pain, headache, buzzing, vertigo, and nausea. The exostosis was as hard as ever, but seemed to be a little smaller and very slightly movable. It was suspected that it might be a pedunculated exostosis and removal suggested. The operation was agreed to and performed in December, 1923. A stout wire snare brought it away remarkably easily. The attachment was by a moderately broad base to the superior posterior meatal wall at the junction of the cartilaginous and bony portions. The ear was packed, bleeding being very slight. The patient was seen again in March, 1924, and the meatus was found to be perfectly healed and without any sign of recurrence. Indeed, one could not recognise any indication of the spot from which the neoplasm had been removed. The membrana tympani was a little thickened but of normal inclination, and the hearing for the whisper was 15 feet for either ear.

FIG. 2.



Tumour of external auditory meatus. × 120.

The growth was bisected with difficulty with a scalpel, and the cut surface appeared to be that of a dense fibroma. It was handed to Dr. Butterfield for microscopic examination, and the following is his report :—

"The specimen as received for examination consisted of a plaque of dense tissue removed from the surface of the external auditory meatus. It was pale in colour, distinctly hard, and measured approximately half an inch in diameter with a thickness of an eighth of an inch. This was embedded in paraffin through carbon bisulphide, and sections cut in the usual manner at right angles to the skin surface. The stratified squamous epithelium shows under the microscope no break in the continuity of its surface and no changes in the character of its constituent cells. Its outline on the deep surface is clear and definite, and immediately under it is a layer of dense fully-formed connective tissue showing here and there collections of small round cells. The whole of the remainder of the tissue consists of an irregular meshwork of dense fully-formed connective tissue fibres containing in its spaces cells of a totally different character, which vary in their arrangement from small solid masses to irregular tubular glands lined with a layer of cells varying in thickness. These cells show nothing in their appearance suggestive of a connective tissue origin, and their demarcation from the strands of connective tissue in which they are embedded is clear and well defined. They show a tendency to stain with alkaline rather than with acid dyes, and the nucleoli are hardly differentiated at all from the body of the nucleus. The blood-vessels seen have all a quite definite structure, and there are nowhere any signs of the tumour cells themselves acting as the walls of blood spaces.

The sections under a moderate magnification give an impression of a general resemblance to a rodent ulcer without the density and regular staining which characterise that condition, while the appearance and arrangement of the cells suggest very strongly that their origin is from the ceruminous glands of the external auditory meatus. The photomicrograph (Fig. 2) shows a characteristic portion of the mass of the tumour."

BAYER "G. 1919" IN THE TREATMENT OF FILARIASIS.

By GEORGE C. LOW, M.D., C.M. EDIN.,
F.R.C.P. LOND.,
SENIOR PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES, LONDON;
LECTURER AND CONSULTING PATHOLOGIST, LONDON
SCHOOL OF TROPICAL MEDICINE;

AND

W. ERNEST COOKE, F.R.C.S. IREL., D.P.H.,
HOUSE PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES.

THE treatment of filariasis is still in an unsatisfactory condition. Several papers on the subject, dealing with the exhibition of drugs, such as antimony tartrate, arsenic, emetine, &c., in such cases have already been published by one of us[1] (G. C. L.). So far no drug has given satisfactory results.

The success which followed the treatment of trypanosomiasis with the substance known as Bayer "205" inspired the hope that a new preparation, known as Bayer "G. 1919," manufactured by the same company and recommended as effective in filariasis, might lead to equally satisfactory results. Through the kindness of Dr. P. H. Manson-Bahr a supply of this drug was obtained, and a suitable case of filariasis being under our care at the time, we decided to give the new preparation a thorough trial.

Bayer "G. 1919" is a coarsely granular powder. It is easily soluble in water or physiological salt solution, but the solution must not be kept for more than 24 hours. It is stated to be effective against syphilis, but is not as potent as salvarsan. Administration is by intravenous methods, and the amount recommended for each injection is 0·5 g. dissolved in 5 c.cm. of sterile distilled water. One injection may be given weekly for ten weeks—e.g., a total of 5 g. in all. If given in larger doses nephritis and dermatitis may be caused, therefore it is not advisable to exceed the dose of 0·5 g.

Two Recorded Cases.

Two cases are on record in which the drug has been given.

CASE 1.—A patient with an infection of *Filaria loa*, in February, 1922, developed neuritic pains subsequently to the exhibition of the drug, but after-treatment is reported to have had no further symptoms of the disease.

CASE 2.—A lady with "wandering filariæ and embryos in her blood." After treatment no more microfilariæ were noted. Later she suffered from jaundice, but this was not definitely attributed to the drug.

In the trial of a new preparation one cannot too fully emphasise the importance of conducting prolonged examinations, hence on this occasion we followed our usual custom of examining measured quantities of the blood before, during, and after treatment to demonstrate what effect, if any, the drug had upon the embryos, which would, of course, disappear in the event of the adults being killed. We believe that this is the only way to determine the efficacy or otherwise of the substance undergoing the test.

---

[1] THE LANCET, 1920, ii., 551; 1921, i., 221.

The Selected Case.

The details of the case selected for treatment were as follows:—

History.—A. R., 42, Indian native, born in Calcutta, where he lived till going to sea ten years ago. Has sailed a lot between India and the China Coast. Last voyage from Bombay to England.

Previous Illnesses.—Syphilis eight years ago; no history of malaria or dysentery.

Present Illness.—Patient quite well on leaving Bombay, but after a fortnight at sea a pyrexial attack developed which lasted about three days. Since that date some fever at night and pain after micturition.

Examination.—There was little or nothing to make out in the patient's physical examination. A few enlarged glands on left side of neck. Some bronchitis present. Systolic murmur at apex of heart. Abdomen: spleen and liver not enlarged. Glands in both groins enlarged and shotty. Scrotum enlarged, lymphatics on both sides varicose. Slight hydrocele on left side with enlargement of left testis. C.N.S. nothing abnormal.

Blood.—Red corpuscles, 4,900,000; white corpuscles, 9000; Hb 100 per cent. Differential: P.M.N. 77 per cent.; L.M., 10 per cent.; L., 11 per cent.; E., 2 per cent. Night blood: Many embryos of *Filaria bancrofti* present. No malarial parasites; Wassermann reaction negative.

Fæces.—No ova, no protozoa.

Urine.—Sp. gr. 1018, alkaline, no sugar; albumin, a trace; phosphates present; no blood; a few pus cells; no embryonic filariæ.

Sputum.—No tubercle bacilli.

Filarial Condition.—Hydrocele and enlarged testis very likely filarial, as also the dilated lymphatics of scrotum.

After the first few days in hospital the chest condition improved; the pain on micturition disappeared, and the urine became free from albumin and pus cells, remaining so up to the date of commencing treatment.

As the case presented such a heavy filarial infection, as evidenced by the numerous embryos in the blood, it was resolved to carry out an accurate analysis of those, both before, during, and after the administration of the drug.

The test was started on May 23rd, 1924, and continued without intermission until August 11th, a period of 11 weeks and 3 days, 20 c.mm. of blood being taken at 11.55 each night, and the number of embryonic filariæ in this amount counted on the following morning. Weekly injections of the drug were given, the injection being given between 2 and 3 P.M. Previous experiences have shown that for certain unknown reasons the number of the embryos in the blood varies from time to time. They may almost completely disappear for a period, quite irrespective of treatment, and it is well known that an attack of lymphangitis may cause their complete disappearance from the peripheral circulation, with no subsequent return.

Account of the Test.

All the injections were well borne with the exception of that on June 18th. This injection, the fourth of the series, was followed in one hour by a rise of temperature to 100° F., with a slight rigor; pulse 112. By night the temperature had again fallen to normal. On no other occasion did those symptoms recur. With two exceptions the range of variation of the temperature was from 97° to 99° during the period of the trial, the rise taking place in the evening. The first exception was that mentioned above, when the rigor occurred. The second was on July 12th, when at 10 A.M. it reached 100°; pulse 96. No factor to account for this could be found. An injection had been given the previous day, but it had been well borne.

The infection was a heavy one. Before treatment was begun the average number of embryos in the 20 c.mm. of blood taken each night was over 230. The usual variations in the number occurred from time to time, sometimes the rise or fall on successive nights was extreme, as on May 28th–29th, 264 to 136; July 11th–12th, 200 to 75; July 9th–10th, 100 to 215; and August 2nd–3rd, 88 to 192. The second night (May 29th) after the first injection the first marked fall appeared. This, though it raised hopes of success at the time, did not occur again, but on the contrary the variations after subsequent injections always remained small, some even showing an upward tendency.

It was observed that during the time of treatment the average number of embryos per night was less than that of the short period preceding the first dose of the drug. No steady diminution took place, however, such as would have been expected were the drug acting in a beneficial manner and killing the adults; but it is noticeable that even after the prescribed course had been completed the counts for August 3rd and 4th showed a marked rise again, the figures being 192 and 172 respectively.

As the drug had been stated to cause nephritis and dermatitis a watch was kept upon the condition of the skin and kidneys. No symptoms nor signs of dermatitis appeared. On June 23rd a slight trace of albumin and a few pus cells appeared. The trace of albumin persisted till the termination of treatment, while the pus disappeared almost at once. No casts were observed at any time. The kidneys, therefore, cannot be said to have been unduly affected.

During the week preceding the last injection the patient complained of slight dizziness, some soreness of the mouth, and anorexia. A few small, whitish, stomatitic patches appeared on the buccal mucosa, but none of these symptoms persisted more than a few days. A steady diminution in weight to the extent of 4 lb. in all was manifest during the final period of treatment, but on its conclusion the patient's general condition was good, and he felt in better health than on admission to hospital.

Conclusions.

In conclusion, it will be seen that the drug has failed to justify the claim of its producers that it has a beneficial effect in cases of filariasis (*F. bancrofti* infection), and the hope that it would prove as effectual in this sphere as Bayer "205" in trypanosomiasis has yet to be demonstrated. The improvement noticed in the patient's general condition was observed before the test was commenced and was probably due to the diet, rest, and care received in hospital.

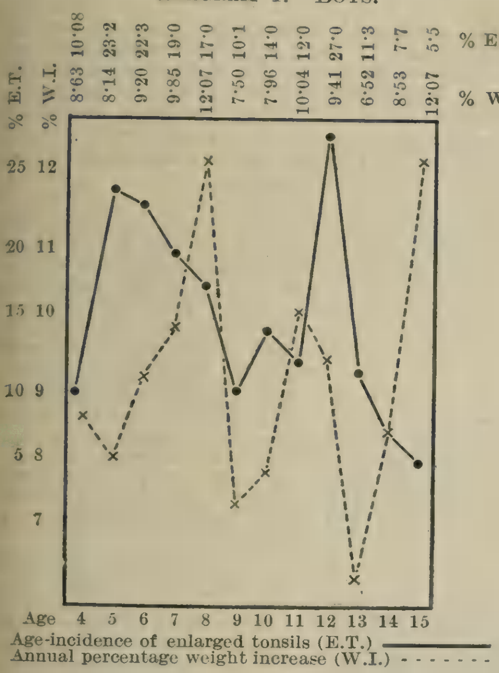
SUGGESTIONS ON THE ÆTIOLOGY OF HYPERTROPHY OF THE TONSILS.

By H. LESLIE CRONK, M.D., D.P.H. Camb.,
ASSISTANT SCHOOL MEDICAL OFFICER, CORNWALL.

Henoch,[1] in 1889, recognised that the cause of hypertrophy of the tonsil in children was obscure. He says: "As the result of the frequent occurrence of these attacks of inflammation, the tonsils may in time become hypertrophied. As a rule, however, I have seen this hypertrophy in children who had not suffered at all, or, at least, very seldom, from sore throat. I have also been able to ascertain by definite symptoms the presence of scrofula as a predisposing cause only in a few of the cases, although its presence is often assumed without sufficient reason." Garrod, Thursfield, and Batten[2] state that the cause of enlargement of the tonsil is the same as that of adenoids; with regard to the latter they say: "At present the trend of opinion is in favour of the hypothesis that the enlargement of the lymphoid follicles of the naso-pharynx is a response to infection." Medical opinion has thus not progressed very far in this matter since Henoch wrote.

This view of the inflammatory origin of the enlargement of the tonsils and adenoids has, in my opinion, been the cause of many needless operations. Lately there has been some reaction from the view that hypertrophy was sufficient reason for enucleation of the tonsil; it has been pointed out that the tonsil as, in all probability, some function, although bscure, in the bodily economy, and also that hyper- rophy is not an unequivocal sign of disease. The ttitude of hostility towards the tonsil, now happily essening, has, I think, its origin in a limited con- eption of its functions, which, from its structure nd its situation, appear to be those of a lymphatic land so situated that it may entrap organisms in e oral cavity. It has been forgotten that to do s duty it has not only to destroy organisms, and so id in producing immunising bodies, but also to eep up the supply of lymphocytes in the blood. It in this last, so obvious but so neglected, function at the reason for hypertrophy lies.

DIAGRAM 1.—BOYS.

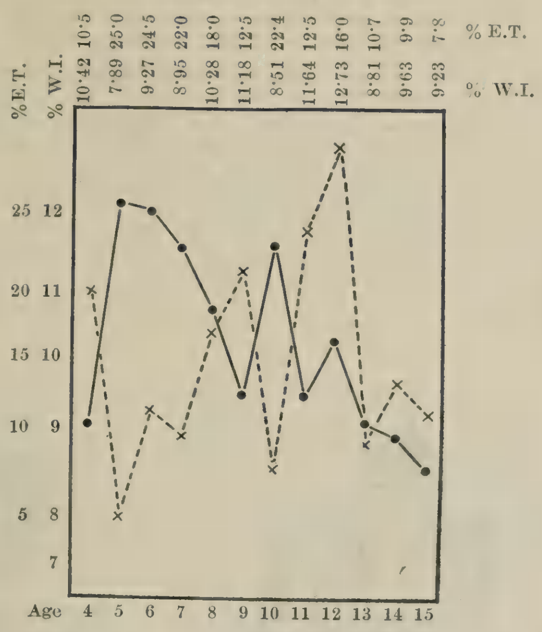


In examining school-children I have repeatedly oticed that enlarged tonsils are more common at me ages than at others, and that many children ith such enlargement are the picture of health, and e even better nourished than the average child. uch children frequently show no pathological largement of the tonsillar lymphatic glands, and their mouths and history present no cause for ypertrophy on the infection theory. Other children gain, equally fat and healthy, will show evidence glandular enlargement elsewhere without hyper- ophy of the tonsil. These cases seem to me to be arallel to one another, the only difference being in e situation of the lymphatic tissue which becomes ypertrophied.

Hypertrophy of the tonsil has been shown to be ue to excessive formation of lymphocytes in the gan, and the point at issue is the reason for the creased supply of these cells. They are not phago- tes, and the theory that they produce an anti- acterial substance or antitoxin has no experimental idence in its favour. Our knowledge of the function these cells is not complete, but from recent searches by Cramer[3] and others it appears that they e of great importance in nutrition. Cramer holds at lack of vitamin B causes its symptoms of inani- on by its atrophic action on the lymphoid tissue the intestine, while Carrell[4] has shown that fixed ssue cells cannot absorb nutriment for their growth nless lymphocytes are present so to alter the sub- ances carried by the serum that they can be utilised y the tissues. If this is true, in periods of growth, mphocytes must be in abundance, and for their roduction lymphatic tissue must proliferate.

Now growth is not a linear function of age, but takes place more rapidly at some ages than at others. Again, the presence of tonsillar hypertrophy is also not a linear function of age. The growth-rate[5] at various ages from 3 to 15 years has been charted in the accompanying diagrams, on which is also represented the age-incidence of hypertrophy of the tonsil.[6] From these diagrams it is seen that the two main maxima of increase of weight occur two to three years after a maximal incidence of tonsil hypertrophy; this occurs in both sexes, although the curves of growth are not identical.

DIAGRAM 2.—GIRLS.



When the rise of tonsil incidence is small (as at 10 years of age in boys and 12 years in girls) it is followed by a small rise in weight increase at a short interval; when the rise is greater (as at 10 years of age in girls and 12 in boys) so is the rise in weight increase higher and the interval longer. There seems more than mere coincidence in this, and the suggestion is obvious that increase of lymphoid tissue is a necessary preliminary to growth in weight, and that the tonsils in this matter hypertrophy simply in order to take their share in the production of lymphocytes and not as a result of infection. If excised they will always show the presence of organisms in the crypts, but so will any tonsil after the first few days of life, and such invasion does not constitute infection. Growth is a primitive function and is correlated with the primitive function of the tonsil, which is that of a producer of lymphocytes. I do not say that many hypertrophied tonsils are not diseased; it would be reasonable even to suppose that rapidly growing organs should be more susceptible to bacterial attack, but I believe that all are not diseased. If this is admitted the cause of the hypertrophy must be sought elsewhere, and the evidence points to some connexion with the influences, at present obscure, determining the periodic spurts in the formation of new tissue.

Clinical and Laboratory Notes.

A CASE OF AORTIC ANEURYSM.

By C. Burgoyne Pasley, F.R.C.S. Irel.,
CHIEF SURGEON, PERAK, FEDERATED MALAY STATES.

The photographs which accompany this note illustrate a very remarkable case which came under my notice in the Ipoh Hospital, Perak.

The patient was a very debilitated Chinaman, who furnished a history of a gradually enlarging tumour with considerable pain. There was also a very definite history of long-standing and untreated syphilis. The Wassermann blood-test was positive, and there was marked evidence of atheroma. The enormous tumour showed marked expansile pulsation, on auscultation over it a very loud bruit was audible, and puncture with a needle proved the sac to contain blood. On these findings the diagnosis, which was confirmed post mortem, was made.

Fig. 1.

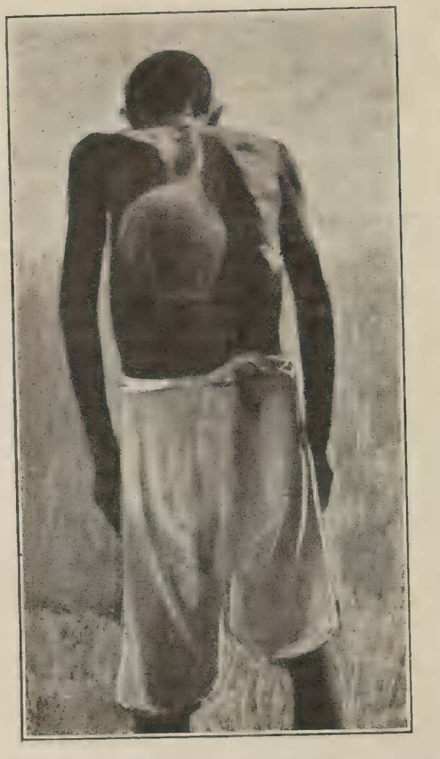

Fig. 2.

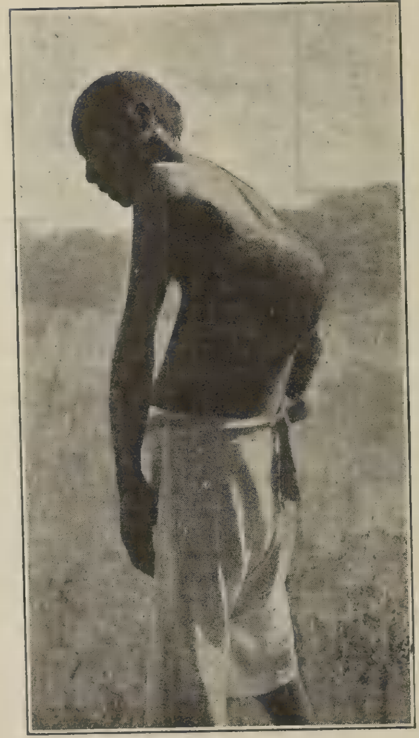

Reproductions of photographs of a case of aortic aneurysm, showing dorsal view and lateral view of tumour.

Aneurysm is quite a common disease among the Chinese mining coolies, the vast majority of whom suffer from untreated syphilis. Their avocation, which entails the carrying of heavy burdens, is no doubt an important contributory cause of aneurysm. I have seen and operated on many such cases. A remarkable case of the kind operated on by me in Kuala Lumpur in 1917 was that of an enormous aneurysm of the left common carotid. I tied the artery at the arch of the aorta by opening up the anterior mediastinum. The patient survived for eight days, but died from œdema of the brain.

A CASE OF UVEO-PAROTITIC PARALYSIS.

By Macdonald Critchley, M.D. Brist.,
SENIOR HOUSE PHYSICIAN, NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, LONDON;

AND

Percy Phillips, M.Sc., M.B., Ch.B. Brist.,
SENIOR ASSISTANT MEDICAL OFFICER, SOUTHMEAD HOSPITAL BRISTOL.

The syndrome iridocyclitis-parotitis-polyneuritis i sufficiently rare to justify the publication of anothe case. The recognition of this disease is attributed t Heerfordt,[1] and other cases have been recorded b Mackay,[2] Feiling and Viner, Daireaux and Pechin Brewerton and Dopter.[3] The name "Uveo-parotiti paralysis" we owe to Macbride,[4] who published a ver complete account of one case.

Clinical Note.

The present case occurred in a married woman of 5 who was admitted to Southmead Hospital, March 18th las complaining of arthritis of her knees and intense dryness the mouth. Two years ago the right side of the face bega to swell but caused her no pain. Dryness of the mout appeared and became muc worse three months later, whe the left side commenced to swel For the past six months sh has suffered from soreness her eyes, photophobia, lacryma tion, and mistiness of visio She has lost weight during t past two years. Her previo illnesses included an operatio for vaginal hæmorrhage pe formed when she was 25, in whi both ovaries were removed. S had a "nervous breakdow in 1921. Her family histo revealed nothing of importan except that a sister died diabetes and a brother of phthis Patient was a thin, anæm woman, looking older than h age. Her face was somewh asymmetrical and there w marked ptosis with so marginal blepharitis. There w no mental or temperament abnormality.

Cranial Nerves.—The fields vision were full, but corne opacities did not permit a thorough ophthalmosco examination. The pupils we small and equal: circular shape, central in position, b there was some slight irreg larity in the edges. Reacti to light was sluggish, and the was no reaction on accomm dation. The eye movemen were normal; ptosis was prese especially in the right e Jaw movements and fac sensibility were normal. Th was some facial asymmet the left naso-labial fold be more prominent than t right. Voluntary and emotio movements were full a equal. Taste was unimpair Hearing was somewhat po bone conduction being bet than air. Weber's test was normal. There was no tinnit Patient complained of some dysphagia. The eleventh a twelfth nerves were normal.

Motor System.—The musculature was everywhere poo developed, and there was distinct atrophy, localised to t interossei, the dorsal thumb muscles, and the flexor bre pollicis on both sides. No fibrillation was noted. Mo power was feeble in the hands and extensors of the elbo Tone was normal; coördination good. No involunta movements. In the legs all movements were present but somewhat feeble.

---

[2] Mackay, G.: Trans. Ophthal. Soc., 1917, xxxvii., 208.
[3] Dopter: Gaz. des hôp., 1904, lxxvii., 857.
[4] Macbride, H. J.: Jour. Neurol. and Psychopathol., 19 vi., 242.

Sensory System.—Responses to light touch, pin-prick, heat and cold, passive movements and alterations in position were everywhere normal. There was no appreciation, however, of a vibrating tuning-fork applied to the ankles.

Reflexes.—All tendon-jerks were present. No abdominal reflexes were obtained; plantar stimulation evoked a flexor response.

Trophic.—There was an operation scar over the abdomen and a mark due to an old electric-battery burn. The knees showed some arthritic changes. No cutaneous eruption was found.

Lungs.—At both apices the breath sounds were harsh and vocal resonance was increased.

Parotid.—There was a visible enlargement of both parotid glands, especially the right, involving all lobes. They were hard, non-fluctuating, and painless on palpation. The overlying skin was not involved. No other lymphatic or salivary glands were enlarged. Spleen and liver were not palpable.

Eyes.—Both eyes, especially the right, showed some mucopurulent conjunctival exudate. The irides were muddy and the pupillary margins a little irregular. Both corneæ were hazy. Pupillary reaction was lost on accommodation, and was sluggish to light. On dilating the pupils a circle of pigment was seen in both eyes on the anterior lens capsule at the site of former posterior synechiæ. Photophobia and blepharitis were present.

Teeth had all been extracted over three years ago.

Examination of a blood-film showed a normal leucocyte count, the red cells numbering 3,500,000. Wassermann reaction was negative in the serum.

Discussion.

It appears that the symptoms in uveo-parotitic paralysis may appear in any order; the facial muscles are the most usually affected, but in this case there was but little impairment of the seventh nerve. Dysphagia occurred in this case as in those reported by Macbride and Heerfordt, though this symptom might possibly be due to the dryness of the mouth. Macbride called attention to weekly bouts of pyrexia as in Hodgkin's disease: the present case showed a constant evening rise of temperature up to 100° to 100·5° F.

Points of special interest in this case are: (1) the preponderance of the right-sided manifestations; (2) the slight involvement of the cranial nerves and the mildness of all subjective phenomena; (3) the absence of any rash, as reported by Feiling, Viner, and Brewerton; (4) the association of uveo-parotitic paralysis with absence of the ovaries.

The nature of this disease is almost certainly that of a chronic infection, although the exact ætiology is unknown. Syphilis appears to take no part in the pathogenesis, neither does the previous occurrence of mumps. In our case the pulmonary signs, the pyrexia, and the family history suggest that tubercle might be the causative agent, but the coexistence of a septic arthritis rather obscures the picture.

Medical Societies.

MEDICO-LEGAL SOCIETY.

A MEETING of this Society was held at 11, Chandos-street, in the rooms of the Medical Society of London, on Oct. 21st, Lord Justice ATKIN, the President, being in the chair.

Prof. HARVEY LITTLEJOHN read a communication on

Judicial Hanging as a Humane Method of Execution.

He said that he had recently been able to examine ully six cases of execution, and he thought that the details were of enough scientific interest to be worth recording. He then described in detail the procedure adopted and the post-mortem findings in these cases. The drop used varied from 6 feet to 7¼ feet, and n every case death appeared to be instantaneous. n five cases no movements at all were perceptible; n one case a few convulsive movements of the houlders were seen. In most cases the heart continued to beat vigorously for about 10 minutes, giving a strong radial pulse of 80–150 beats per minute at first, but later becoming irregular and topping altogether after 15 to 20 minutes. In one ase the heart appeared to stop immediately. The odies were allowed to hang for one hour before eing taken down. Post-mortem examination showed onsiderable injury to the muscles of the neck, and n five cases dislocation of the spinal column by eparation between the second and third cervical ertebræ. In one case the body of the third vertebra was fractured and dislocation occurred lower down. n some cases the spinal cord and membranes were orn across; in others they appeared intact. After eference to the older and less humane method of anging by strangulation without a drop, and to the methods used in other countries, Prof. Littlejohn oncluded by saying that in his opinion the modern method used in this country was the most humane f all. It was performed very expeditiously (the whole proceedings only taking a few seconds), was ainless, and undoubtedly caused instant death.

Sir BERNARD SPILSBURY described a recent case of udicial hanging in which the post-mortem findings osely resembled those described by Prof. Littlejohn xcept that the spinal column was dislocated between he sixth and seventh cervical vertebræ, as well as between the second and third. The second dislocation might have occurred on a rebound from the first drop. Death appeared to be instantaneous.

Sir WILLIAM WILLCOX agreed with Prof. Littlejohn that judicial hanging was a painless form of death and that the victim immediately became quite unconscious even if convulsive movements were shown. He considered it the best method of execution, and more reliable than electrocution.

Earl RUSSELL considered that a better method, giving less unpleasant anticipation for the victim, and a less disagreeable spectacle for the onlookers, would be the introduction of coal gas into the prisoner's cell at night during sleep. This would be painless and not disagreeable.

Dr. G. ROCHE LYNCH said he thought it unwise to leave the decision as to the length of drop needed to the executioner.

Dr. JAMES SCOTT said that he had seen many executions, and fully agreed with Prof. Littlejohn that hanging was a quick and sure method of execution with no evidence of suffering. The length of drop was now regulated according to tables drawn up by a committee which had investigated the subject. He considered the methods used in other countries less satisfactory.

The PRESIDENT closed the discussion by remarking that he thought it most important that the public should feel assured that judicial hanging was painless, and that complete unconsciousness, if not death itself, was instantaneous. He thought that provision by the authorities for post-mortem examination by competent persons, with publication of the results, would allay a good deal of public unrest. He considered Lord Russell's proposal objectionable, because if the prisoner did not know on which night he was to be poisoned he would lie awake many nights expecting death. If, however, he was forewarned, he would certainly not sleep on the given night, but would be slowly suffocated while conscious.

Prof. LITTLEJOHN, in reply to a question, said that even the thickest neck could be overcome by suitably lengthening the drop, and that, as carried out nowadays, no accidents occurred.

Prof. LITTLEJOHN then read a paper entitled

What is a Fatal Dose of Strychnine?

describing cases of fatal poisoning from known small doses of strychnine.

CASE 1.—A woman of 25 swallowed a powder containing 1 gr. of strychnine. This powder had been dispensed by a chemist who kept his strychnine bottle next a bottle of exalgin and had used strychnine in mistake for exalgin.

The powder was swallowed with water. After five minutes the patient felt sick and unwell, and was helped to bed. After 15 minutes she complained of pain at her heart, and passed into a general convulsion lasting one and a half minutes. She then expressed a fear of death, and 30 minutes after taking the powder died in a convulsion. Post mortem strychnine could be detected in the blood and in the stomach, but not in the stomach contents.

Case 2.—A woman of 36 consulted a doctor, who prescribed for her a mixture of liq. arsenicalis ½ oz., and liq. strychninæ hydrochlorici ½ oz., of which six drops were to be taken thrice daily. The patient finished the liquid in the bottle without ill-effect, but later on, wanting a further dose, she noticed a white deposit in the bottle, added some water, and drank the contents. Two hours and 20 minutes later she died after several convulsions. On analysis the remaining contents of the bottle were found to contain 4 mg. of strychnine. The total amount originally present was $2^1/_5$ gr., but it is uncertain how much of this was swallowed in the fatal dose.

The case was an illustration of the danger of prescribing powerful drugs in drop form instead of in dilute solution, and also showed an inexcusable error of the prescriber, and especially of the chemist, in dispensing two incompatible drugs. It was well known that alkaloids are precipitated by alkalies from solutions of their salts, and in this case strychnine was precipitated from its hydrochloride solution by the alkaline liq. arsenicalis. When the patient added water and shook the bottle she formed a suspension of this precipitated strychnine which proved fatal.

Case 3.—A naval officer of 25 wanted a "pick-me-up" and was given 1 drachm of liq. strychninæ hydrochlorici by a ship's doctor who misread the dose printed in his Pharmacopœia. After 20 minutes the officer laughingly complained, "That was strong stuff. I can't walk properly now." The doctor became suspicious, discovered his error, and gave the officer salt and water and tartar emetic, which produced some vomiting. In spite of this, and of artificial respiration, the officer died from respiratory failure three-quarters of an hour after taking the poison and after only one convulsion. One drachm of liq. strychninæ hydrochlorici contains 0·55 gr. of strychnine.

Case 4.—A boy, aged 3½, was found playing with some tabloids of Easton's syrup. After an interval he had convulsive seizures and died on arrival at hospital not more than one and a half hours after taking the tabloids. As far as could be ascertained, he had taken two or possibly three tabloids, equal to a total of 1/32 or 1/20 gr. of strychnine.

Case 5.—A child, 18 months old, was found eating laxative pills which the mother kept on a table at her bedside. The child was thought to have eaten nine pills, each containing strychnine gr 1/60, belladonna gr. 1/8, and aloin gr. 1/5. Convulsions began within 15 minutes, and in spite of medical treatment by 1/20 gr. apomorphine and later chloroform, death occurred 2 hours 20 minutes after taking the pills. Nine pills would contain 1/7 gr. of strychnine.

Prof. Littlejohn pointed out that in the recorded cases of strychnine poisoning the fatal dose varied considerably according to the constitution of the individual and the circumstances of the administration. Recovery had been recorded from doses up to 40 gr., while, on the other hand, ¼ gr. had been said to prove fatal to an adult. This latter case was admittedly uncertain, and the next smallest fatal dose recorded was ½ gr., which was said to have killed a Dr. Warner in 20 minutes. Here, again, the evidence as to dosage was by no means definite, but the case of the naval lieutenant recorded above (0·55 gr.) afforded definite corroboration of the fatal dose of ½ to 2 gr. usually given in books. Apart from the question of fatal dose these cases provided striking illustrations of ways in which accidental strychnine poisoning might occur, and of the care needed in prescribing the drug, or allowing it to come within the reach of children.

Sir William Willcox pointed out that strychnine was one of the most stable of poisonous alkaloids, and mentioned that in the viscera of a fox poisoned 20 years ago and since kept in his laboratory, strychnine could still be detected with ease. The fatal dose of snrychnine appeared to be proportional to body-weight atd hence doses which were medicinal for an adult might be fatal to a child. Both the speed of action and the fatal dose probably depended on the method of administration, solutions being quicker and more deadly than the solid form, since their absorption was more rapid and the toxic effects were probably proportional to the concentration in the blood at any instant. Idiosyncrasy undoubtedly occurred with this drug, and he had seen cases in which adults taking 1 drachm of Easton's syrup as a tonic ($\frac{1}{32}$ gr. strychnine) three times a day suffered from spasms in the legs and other symptoms, and were really on the verge of poisoning. Dixon Mann had stated that if excretion in the urine was slow toxic effects were more marked, and Sir William Willcox thought that in such cases the fatal dose might be considerably less than ½ gr., especially if taken in solution on an empty stomach.

Dr. C. Owen Fowler pointed out a possible danger in the dispensing of strychnine due to its tendency to crystallise out round the stoppers of bottles. Such crystals falling off as the solution was poured out might easily lead to excess of the drug in a prescription.

Mr. John Webster quoted a case of tolerance to the drug in which a woman took increasing doses of strychnine for two years before her death. In the last few weeks these doses rose to from $\frac{1}{10}$ to $\frac{2}{5}$ gr. per day without the appearance of symptoms, perhaps partly owing to the presence of paraldehyde in the prescription. Post-mortem analysis showed only very faint traces of strychnine in the liver and stomach, too small to estimate, although the large doses were taken up to death.

Dr. W. B. Purchase pointed out that in calculating fatal doses allowance should be made for such amount of the poison as was vomited, and asked if these amounts had been subtracted in the cases quoted.

The President emphasised the importance of the question from a medico-legal point of view, and pointed out that the discovery that ½ gr. had killed one adult did not prove that a similar dose would kil any given individual, and did not necessarily show the minimum fatal dose or the maximum dose that could be tolerated. Owing to the importance of tolerance as well as idiosyncrasy great accuracy was needed in discussing the subject, and all light on it was helpful.

Prof. Littlejohn, in reply, said that idiosyncrasy was unquestionably shown with all drugs. Fo instance, with strychnine paralysed persons migh need very large doses. Hence the individual must always be considered. Tolerance, however, was a different question, and, in his opinion. no habi tolerance could be formed to strychnine, howeve much was taken. In answer to the constant question What is the fatal dose of strychnine ? we now had a really authentic record of ½ gr. causing death in a healthy adult.

LIVERPOOL MEDICAL INSTITUTION.

Encephalitis Lethargica.

A meeting was held on Oct. 23rd, when Dr. Gordo Gullan read a paper on a Clinical Study of 62 Case of Encephalitis Lethargica. He began with a historica note of the disease, and described various types an cases. Onset, special symptoms, and syndrome results with sequelæ, diagnosis, prognosis, and treat ment were also set forth.

Dr. Henry Cohen expressed surprise that pain wa present in only one of the 62 cases. In his experienc severe pain, probably of thalamic origin, was n uncommon. Pain frequently preceded the onset myoclonus and had been mistaken for an acut abdominal lesion in some recorded cases. Extensiv classification was to be deprecated owing to th innumerable varieties encountered. Walsh's classifica tion, in which the symptoms and signs were regarde as (*a*) evidence of general infection and toxæmi (*b*) evidence of exaltation and depression of the nervo system, either general or local, was suitable except tha thereby the common manifestations—for example, the oculo-lethargic and the myoclonic types—might be insufficiently emphasised. In the differential diagnosis, meningitis—tuberculous and syphilitic—could in the majority of cases be excluded by examination of the cerebro-spinal fluid. Difficulty in diagnosis occasionally occurred in cases of (i.) sinusitis, especially frontal sinusitis associated with brain abscess, (ii.) infective endocarditis of the cerebral type, (iii.) uræmia especially associated with myoclonus, and (iv.) post-diphtheritic paralysis. Papillœdema was so rare as to suggest intracranial neoplasm or abscess, though undoubted fundus change occurred in epidemic encephalitis—slight in degree and rarely. Dr. Cohen considered that the figure given by Dr. Gullan for complete recovery (50 per cent.) was too high. Treatment of the sequelæ was disappointing, though hyoscine hydrobromide in the Parkinsonian syndrome, luminal in the myoclonic types with pain, and Lust's treatment in cases presenting reversal of sleep rhythm were useful in many cases. Pitcairn's method and magnesium sulphate injections were disappointing.

Mr. C. O. DAVIES read a note on Pharyngeal Diverticula with an account of two cases recently treated at the Liverpool Royal Infirmary.

CARDIFF MEDICAL SOCIETY.

A MEETING of this Society was held on Oct. 15th, when Dr. R. M. F. PICKEN, M.O.H., Cardiff, spoke on

Present-day Health Tendencies in Cardiff.

After referring to the importance of the medical profession reviewing locally from time to time the results of public health activities, Dr. Picken emphasised the important use of the statistical method of inquiry and dealt with the absence of reliable local statistics of sickness, as a result of which information in the mass was available only through death returns. The death-rate in Cardiff had fallen more rapidly than in England and Wales generally since 1851, and at the present time Cardiff was favourably placed in relation to the acute infectious diseases. So far as infant mortality was concerned, there had been a satisfactory decline which was shared in almost equal degree by all the other towns of importance. Dr. Picken considered at some length the various explanations which had been given for this decline, and mentioned that in his opinion the continuous fall in the birth-rate was probably the most important factor. Examples were given of towns where there did not appear to be any definite correlation between a low birth-rate and a low infant mortality, but in places like Bradford and Huddersfield this might be due to special circumstances affecting the employment of married women. The fact that the decline of the infant mortality commenced 25 years after the commencement of the fall in the birth-rate was not necessarily an argument against the former being the result of the latter. The problem of tuberculosis was dealt with at some length, and it was shown that in Cardiff the death-rate from pulmonary tuberculosis, more particularly among males, was actually increasing. Various possible reasons for this were considered, and it was shown that the cause could not be found either in excessive unemployment as compared with other places or in the foreign seafaring population, who admittedly suffered heavily from tuberculosis, or in the migration of the population in such way as to ncrease the number of susceptible persons in the city. The problem remained unsolved. Having dealt briefly with the increase of cancer and the tendency for the male cancer mortality to equal the female cancer mortality-rate, some practical questions affectng the administration of public health and hospitals n Cardiff were discussed, and a plea was made for better local sickness statistics and greater use of the general practitioners' opportunities for gathering and pooling information which might solve some of the problems touched upon.

LUNACY LAW AND ADMINISTRATION.

OPENING SITTINGS OF THE ROYAL COMMISSION.

THE first meeting of the Royal Commission on Lunacy Law and Administration and Mental Disorder was held at Old Palace Yard on Tuesday, Oct. 7th. Mr. H. P. Macmillan, K.C., presided.

EVIDENCE OF THE BOARD OF CONTROL.

Sir Frederick Willis, chairman of the Board of Control; Mr. S. J. Fraser Macleod, K.C., and Dr. C. Hubert Bond, Commissioners of the Board, were the first witnesses.

Development and Duties of the Board.

Sir F. Willis said that the Board really had its inception in 1845. It was to consist of three legal members and three medical members. He attributed the state of efficiency in asylums to-day in a large measure to the work of the Board, although, of course, there had been also the growth of a right spirit all through the lunacy system. He spoke of the enlargement of the duties of the Board consequent upon the passing of the Mental Deficiency Act, 1913.

The Chairman said that the class of persons to whom the Mental Deficiency Act related were different from those with whom the Commission was concerned in that inquiry. That Act had created a separate code from the code of lunacy law and administration—a code with which that particular inquiry had nothing to do. He added that he was anxious to appreciate the principles upon which this branch of law had developed. It appeared to him to be a compromise between the liberty of the individual on the one hand and the protection of the public against abnormal individuals on the other, together with the protection of the individual himself against the consequences of his abnormality.

Sir F. Willis agreed, and said that nowadays we looked to the cure of the individual.

The Chairman said that the medical side had shown a progressive effort to improve the conditions under which those of unsound mind were treated and to aid their recovery. He asked if he might take it that the main sources of the existing law were to be found in the Lunacy Acts of 1890–91, with certain amending statutes, and asked also what other bodies or persons were concerned, in addition to the Board of Control, with persons of unsound mind.

Sir F. Willis said that the Lord Chancellor had an ancient jurisdiction which related to the person as well as to the property. Largely his powers were derived from common law. The Home Secretary, of course, had jurisdiction over criminal lunatics. The Ministry of Health had jurisdiction, not over buildings, but over persons.

The Chairman asked whether any disadvantage had arisen from the distribution of functions among these different bodies.

Sir F. Willis thought it desirable that the Board of Control should be able to go to the Minister of Health just in the same way as the Ministry of Health as a department went to the Minister. He agreed that the number of persons found insane by inquisition with whom the Lord Chancellor had to do was decreasing, and that it was a reasonable inference to draw that inquisition is less necessary now than formerly.

Sir F. Willis considered that the present method of dealing with lunatics adequately met the public interest. The categories of patients with whom the Board of Control had to deal were mainly (1) private and (2) rate-aided. In the case of a pauper the justice making the order for detention was required to see the patient. In a private case he need not do so. The places where the insane were dealt with included county and borough mental hospitals (80 per cent.); registered hospitals, where fees are charged, but not with the object of making a profit; licensed houses or private asylums, which are run for profit; naval and military hospitals; criminal lunatic asylums, Poor-law institutions; private single care, and outdoor relief. On Jan. 1st, 1924, there were in the county and borough mental hospitals 103,892 patients (45,897 males and 57,995 females); in registered hospitals, 2139; in metropolitan licensed houses, 1187; in provincial licensed houses, 1610; in naval and military hospitals, 171; in criminal lunatic asylums, 785; in Poor-law institutions, 11,323; in metropolitan hospitals provided by the M.A.B., 5266; in private single care, 417, and insane people receiving outdoor relief, 3544, making a total of 130,334. Boarded-out cases are included in the first category, because they remain on the books of asylums. With regard to licensed houses, Parliament had enacted that the number of these institutions should not exceed the number in existence in 1890. There were now 98 such institutions, including Maudsley, and there were 13 registered hospitals.

Various Safeguards.

Mr. Macleod then described the procedure of petition, and the difference of procedure in the case of a private and of a rate-aided patient. The documents relating to any patient on reaching the Board of Control were carefully scrutinised by an experienced clerk and later by a Commissioner. If they were wanting in any particular they were sent back, and if they could not be amended the order fell to the ground. There was no distinction so far as the Board's scrutiny was concerned between documents relating to private and those relating to rate-aided patients. Perhaps about 12 or 20 certificates a day were referred by the clerk to the secretary for scrutiny, though mostly on technicalities.

Dr. Bond said that it was not always possible to gather from the certificates whether the symptoms there set down were observed by the certifying doctor himself at the time of the examination, and sometimes the facts given did not necessarily indicate unsoundness of mind. The scrutiny of the Board was directed to the whole certificate, but the accent was on the paragraph relating to what was seen by the observer at the time of the examination. The forms were not always examined by a medical Commissioner, but if any purely medical point arose the legal Commissioner would call the attention of his medical colleague to it. He thought that the form could be said definitely to be successful. Doctors did not always grasp the essentials of this certification, but education in this respect was going ahead, especially since some of the medical bodies had established diplomas in psychological medicine. After admission of the patient a description of his mental and bodily condition was furnished to the Board by the medical superintendent within seven days. This was not a diagnosis, but simply a description. The reason for the differentiation between private and rate-aided patients was that in the case of the rate-aided patient, unlike, in some cases, the private patient, it was to no one's interest that he should be unnecessarily detained.

Sir F. Willis said that the real safeguard in all cases was the character and ability of the men at the head of the institutions, not any documentary evidence.

Mr. Macleod then described the system of visitation. In county and borough asylums the visitation took place once a year by two Commissioners. Licensed houses were visited twice a year by the Commissioners and registered hospitals once under statute, but in fact twice. Single-care patients were visited as often as the Board ordered, but in any case at least once a year. The statutory visit must be private, must be made by a legal and a medical Commissioner, without previous notice; many questions were asked of the officers, and every patient was spoken to. Any private patient had a right under the statute to demand a private interview; any private interview asked for by any patient was granted.

Private and Pauper Patients.

The examination of the Commissioners was continued on Wednesday, Oct. 8th.

Sir F. Willis described the procedure followed on the discharge of a private patient.

The Chairman remarked on the curious provision that a patient who had escaped from detention and remained in hiding for 14 days was free from restraint.

Sir F. Willis said that he saw no reason in this stipulation; it was probably an inheritance from the old days of lunacy administration.

The Chairman remarked that there were differences in the procedure of discharge between private and rate-aided patients, and he supposed that here again the reason was that there was no pecuniary inducement on the part of any person to retain the rate-aided patient in an institution.

Dr. Bond remarked, on the subject of medical examinations, that it was a growing practice—and in one hospital the routine practice—for the medical superintendent, on the admission of a patient, to discover the name of his family doctor, if there was one, and inform him briefly as to the facts of detention and invite him, if in the neighbourhood of the asylum, to come in and discuss the case.

Sir F. Willis said that the number of patients sent out on trial in 1922–23 from borough and county asylums was 5525, but a large number had to return to the institutions. On the question of accommodation he expressed the view that mental hospital accommodation was inadequate, and that in a short while the position would be serious, owing, not to any undue increase of insanity, but to the natural growth of population.

The Chairman thought it might be necessary to reconsider the policy which since 1890 had arrested the growth of the licensed house.

Sir F. Willis then spoke about medical certificates. He said that there were very few misdemeanours in this respect under the Act, but difficulty did arise through medical practitioners withholding certification of one of their private patients in order to avoid the stigma of detention. That was a contravention of the Act. The practice of the Board on learning of such a case would be to apply to the Lord Chancellor for an order.

The next question raised was on the provision for insane patients in workhouses. The Chairman said that the workhouse was not the proper place for the reception of patients likely to improve under treatment; if used at all it should be for chronic and hopeless cases.

Sir F. Willis said that his Board would welcome any practicable suggestion for the better use of the total accommodation.

Steps Following the Arrival of the Patient at an Institution.

Dr. Bond, at the request of one of the Commissioners, then detailed how a patient was dealt with on arrival at an institution. A preliminary physical examination was made while the persons who had brought the patient remained on the premises. The patient was put to bed for at least a week, during which time an elaborate examination was made by more than one doctor, and a report sent to the Board of Control. The examination was repeated at monthly intervals, certainly for the first three months, and probably for the first year, and later at quarterly intervals.

Sir Humphry Rolleston asked how often it happened that the second certificate, the first having been given by the family doctor, was given by an expert in mental disorder.

Dr. Bond said that in the metropolis this was very frequent, less so in other parts of the country. Dr. Bond also stated that faulty certificates were extremely few in number compared with the hundreds of thousands of proper certificates which came before the Board.

Sir David Drummond raised the question of the clinical experience of medical officers at mental hospitals, and asked whether it was necessary for such officers to have had a training in a general hospital.

Dr. Bond said that such training was recommended by the Board, though it was not made a sine qua non.

Mental hospital authorities had also been urged to appoint, in addition to their resident staff, certain consulting physicians other than mental specialists —i.e., gynæcologists, and so forth. He doubted, however, whether it would be practicable to lay down a hard-and-fast requirement for clinical experience; visiting committees even as it was did not get sufficient applications when there was a vacancy.

Allegations of Cruelty.

The Secretary of the National Society for Lunacy Reform asked permission to put certain questions, and these were put through the Chairman. The first question was how frequently the Board had to investigate cases of cruelty.

Sir F. Willis said that the Board received a great many complaints of cruelty, chiefly from the patients themselves, in the form of letters. Every case was investigated, if necessary by a sworn inquiry, but in very few instances was the complaint substantiated. In one case only in 1923 an attendant was prosecuted and fined for striking a patient, and there were very few cases, not more than half a dozen a year, in which complaints were found proved and disciplinary action other than prosecution taken. The right of an ill-treated patient to appeal to his doctor was very jealously safeguarded, and in addition to this, the patient could always write to the Board, and, as he had said, every case was investigated. He had heard it stated that some patients were too frightened to complain, but he had not known this to be substantiated. He thought that the surprise visits of the Commissioners did much to allay any uneasiness on this score, for it occasionally happened that the Commissioners on going round the wards were apprised of some case, and held an inquiry forthwith, sometimes on oath.

In answer to a question from the Chairman, Sir F. Willis said that the licensee made the appointment of heads of licensed houses; the licensee need not be a doctor, but the Act required that there must be a resident doctor, and a visiting doctor according to the number of patients. Asked whether he had any statistics of the number of persons who have been discharged from detention on the ground that they were not insane when admitted, he answered: "A very small number." He had had no experience of cases where persons not insane had been wrongly detained in asylums, and he regarded the existing machinery in the matter of certification and provisions with regard to detention as adequately safeguarding the liberty of the subject. On the other hand, if ingenuity could suggest any additional reasonable precautions the Board would not resent them. With regard to curative treatment in the hospitals themselves, the Board had responsibility only in an advisory capacity. The responsibility for the treatment of each individual case must rest with the doctor of the institution. If the Board found an institution lax in this matter they could bring pressure to bear on the medical superintendent or the local authority, but they could not insist that an extra doctor be appointed or a laboratory provided.

EVIDENCE OF THE LORD CHANCELLOR'S DEPARTMENT.

Sir Claud Schuster, Permanent Secretary to the Lord Chancellor, gave evidence with regard to the small number of patients in whom the Lord Chancellor had an interest. These were patients found insane by inquisition—a very small number—and those in whose property the Lord Chancellor had some concern. The Lord Chancellor's visitors were three in number—two medical and one legal—and they visited these lunatics at statutory intervals. Their concern was with the individuals, not with the institutions. Asked whether the Lord Chancellor's ancient jurisdiction was worth retaining, the witness said he was in doubt on that point; it depended on the constitution of the Board of Control, which should include the very highest medical experts on the subject of lunacy, as well as legal men of great eminence. The legal mind was needed to counterbalance the special point of view of the medical. On the whole, he thought that it was as well to continue the Lord Chancellor's functions, which were to some degree those of a champion of these people. He went on to complain of medical certificates, not as to their conclusion, but as to their selection and arrangement of facts leading up to those conclusions, and said that here again the legal mind was necessary to correct and counterbalance the medical.

The Rights of the Confined Patient.

At the resumed sitting on Oct. 21st Sir Claud Schuster, under the same chairmanship, expanded a reply he gave at the previous sitting when he expressed the view that a lunatic in confinement had not been and should not be given the right to demand a public inquiry as to whether he had recovered. The conferment of such a right would be unfortunate. Lunacy was a disease which might or might not be curable, and, like other diseases, its cure or alleviation was a gradual process. It would, therefore, be very difficult in many cases to determine the point at which the patient might be said to have been cured or to have made such progress as to be properly released, and this would be a matter peculiarly unsuited for public inquiry. Moreover, as the function of those who had to determine whether the patient was to be released or further detained was not to investigate any charge against the patient as though he were an alleged criminal, but whether certain action should be taken in his interests and those of the public, the matter was unsuitable for forensic treatment, and it would be very undesirable that the local authority or the person in charge of the asylum should be forced into an office analogous to that of prosecutor. Again, a very large proportion of lunatics considered that they were wrongfully detained, and every one of these people would have the right to demand an inquiry and many of them would exercise it. The question of a lunatic's condition was unsuitable for discussion in public—often unpleasant and sometimes humiliating for the patient and detrimental to his interests.

EVIDENCE OF THE MINISTRY OF HEALTH.

Mr. L. G. Brock, Assistant Secretary to the Ministry of Health, next gave evidence. He said that the powers of the Local Government Board were transferred to the Ministry of Health under the statute which set up the Ministry, while certain powers of the Home Office relating to lunacy and mental deficiency were also transferred from time to time by Order in Council. The powers and duties entrusted to the Minister might be grouped under four heads: (1) The Minister had certain limited powers with regard to the individual lunatic. He had no power to order the discharge of a patient, but he could initiate inquiries on complaint. (2) He was called upon to approve the provisions made by local authorities for the accommodation of lunatics. (3) He had certain powers in relation to the Board of Control. He had power to recommend for appointment the non-legal Commissioners, and to approve other (staff) appointments. He was also responsible for the Board's estimates in Parliament. But, apart from these ultimate sanctions, the Minister had no power to give directions to the Board for any specific administrative act, though, as a matter of practice, the Board invariably met the Minister's wishes. In the daily administrative work of the Lunacy division of the Ministry all patients' letters were carefully read by the responsible officer, and, whenever necessary, the Board of Control was consulted regarding the latest medical report on the patient's condition. There were, of course, a number of chronic patients who wrote regularly, but whose mental condition was fully known to the department, and in other cases the letters bore on the face of them unmistakable evidence of insanity; for example, correspondents frequently complained of being "poisoned by wireless." All letters were carefully examined with a view to seeing if there was any allegation of wrongful detention or ill-treatment. Where the Board of Control had not available a special report from the medical superintendent on any such allegations, or where there was still room for doubt, the Minister asked that the Commissioners at their next visitation should pay special attention to the patient. If a case presented medical as distinct from psychiatric issues which called for investigation a medical officer of the Ministry would be sent to report on it. He added that the correspondence did not afford any evidence whatever of persons having been improperly certified or detained longer than the medical superintendent believed to be necessary, nor had any allegations of ill-treatment been fully substantiated. At the same time it was clear that there were a number of patients in mental hospitals who, though in no sense sane, could be discharged without danger to themselves or the community if their relatives were willing and able to look after them. The exact point at which a person suffering from mental disorder was sufficiently recovered to justify discharge was necessarily a matter of opinion; and some superintendents, mindful of the risk they incurred by recommending discharge prematurely, were more cautious than others. It was also remarkable that in many instances where the relatives were convinced that the case was one of improper detention, the medical report indicated a definitely bad prognosis. The explanation might be that in certain forms of insanity which were slow in development there were periods of quiescence, and as the relatives were only allowed to see the patients on good days they formed an incorrect impression of his mental condition. Other cases developed acute symptoms at an early stage, and, though the prognosis was hopeful, the relatives, having seen the patient violent or raving, had no doubt as to his insanity nor had they much hope of his recovery.

In reply to questions, Mr. Brock said that the Ministry had no alienist on its staff, though one member of the medical staff had had some experience in a mental hospital. He preferred not to answer a question as to the advantages of the Board of Control as a separate authority instead of a department in the Ministry, but he said that the relations between the medical Commissioners of the Board and the medical officers of the Ministry were based on mutual courtesy and administrative convenience, and the result was quite satisfactory.

Mr. H. W. S. Francis, Assistant Secretary of the Ministry of Health, in charge of the Poor-law Division, gave evidence dealing with the functions of the Ministry as the successor of the Local Government Board in dealing with the administration of Poor-law. The department kept closely in touch with the Poor-law authorities through a body of general inspectors, medical officers, and women inspectors. Every Poor-law institution was visited at least once a year. The general inspectors had statutory power to hold inquiries upon oath in matters of Poor-law administration. During the past five years such formal inquiries had been held in two cases in which persons of unsound mind were concerned. The number of insane persons who were inmates of Poor-law institutions, or institutions other than the public asylums, maintained wholly or partly at the cost of the poor-rate, was 27,432, of whom 8763 were inmates of Poor-law institutions provided solely for mental cases, and almost all the remainder were in the sick or other wards of Poor-law institutions. The witness was closely examined as to the procedure at inspections and inquiries, and in one case in which an inquiry as to the ill-treatment of a patient had led to no conclusive result the Chairman remarked that this did not seem very satisfactory.

PROPOSALS OF RELIEVING OFFICERS.

Mr. E. J. Lidbetter, President of the National Association of Relieving Officers, suggested certain proposals to the Commission. He recommended that there should be no difference in the process of certification between the pauper and the non-pauper; except in very rare cases, juveniles should not be certified as insane, nor should cases of senile dementia. The provisions of the Mental Deficiency Act should be amended to enable juvenile pauper cases to be dealt with under its provisions. The Board of Control, or some other authority or commission, should be endowed with powers to determine, under proper safeguards, ambiguities under the statutes and points of law involved. His principal recommendation, however, was that workhouses should no longer be regarded as places of safety for alleged lunatics; asylums committees should be required to provide sufficient reception houses in all urban areas. In such centres there would be sufficient cases to justify and require a rota of justices holding a daily session, and therefore there would be an end to the trouble which frequently at present arose, of securing a justice. The preliminary period of detention under this system need not be as long as three days. The work of such daily centres would be more formal and the investigation of cases would be carried out in a more judicial atmosphere than was possible in the wards of workhouses. There would be at the reception house a resident medical officer available for purposes both of treatment and observation. The reception house would also serve the purpose of a clinic, providing advice and treatment to out-patients. On the recommendation for the discharge of a patient from an institution for lunatics, the staff of the reception homes should be called upon to inquire into and report upon the conditions into which it was proposed to release the patient, and also to make some provision for after-care. The method would also make possible a system of information and record-keeping. In fact, there might be a cross-index containing particulars of every lunatic or alleged lunatic.

The Chairman thanked Mr. Lidbetter for his communication, and said that although the Commission was naturally anxious to do everything that was possible this procedure seemed likely to involve great expenditure.

EVIDENCE GIVEN BY MAGISTRATES.

The Commission sat for the fourth time on Oct. 22nd, under the same chairmanship, when evidence was given by magistrates as to the work done by them under the Lunacy Acts.

Sir John Barnsley, magistrate for the city of Birmingham and deputy chairman of the visiting justices of that city, placed before the Commission suggestions and recommendations made at a special meeting of the Birmingham justices. He said that as a rule he had no difficulty in signing a certificate for detention. He saw alleged lunatics either at his private residence or place of business, or, if they had been taken into custody, he saw them in a private room at the police station. It was no doubt the general practice to see a patient personally before signing a certificate, but it was recommended by the Birmingham justices that a personal interview should be compulsory. It was also recommended that where a doubt existed in the mind of the justice there should be, before final certification, compulsory preliminary observation in some place other than the workhouse or asylum, for instance, an observation clinic. The witness agreed with the Chairman that it should be a place to which there should be a right to send persons of any social position, whether they could pay or not, and that probably the additional expenditure involved might be set off against the saving from the diminution of the probable number of cases which would have to be sent to asylums. Charges might be made for treatment and the institution or clinic could serve as a centre for giving advice and assistance to outdoor cases. It should also be possible for patients to enter the institution voluntarily for a period of treatment without any detention order having been given. If such voluntary cases had dangerous tendencies, some form of compulsory detention would have to be adopted, and naturally such tendencies would be manifest prior to treatment. As to visitation, it was urged that some independent authority should, on the lines provided under the Mental Deficiency Act, periodically visit and report upon all persons detained under the Lunacy Laws. All patients should be visited at the end of the first year, again at the end of the second year, and subsequently every five years. The rota for visitation under the Mental Deficiency Acts was so arranged that one magistrate saw the same person each year and could therefore note the progress that was being made. It would, of course, be necessary to enlarge the judicial authority and increase the number of visitors if that method was adopted.

The Chairman pointed out that the visit would be for the purpose of interviewing the patient who presumably thought he was being unlawfully detained. He had some difficulty in seeing how the visitor would decide that the case was one that ought to be liberated.

Sir John Barnsley replied that he did not suggest the visitor should have power to do anything more than report to the Commissioners that he had visited the case and in his opinion, as a layman, the patient might safely be discharged. It would then be for the Commissioners either to accept that view or to give reasons why it should not be given effect to.

Mr. W. H. Lord, magistrate for the city of Birmingham, was in accord with the views expressed by the previous witness as to observational treatment. His evidence was confined to the admission of patients; he said it was his practice to interview alleged lunatics in the cab in which they were brought to his house by the relieving officer. He had never had occasion to doubt the medical certificates submitted to him. It was proper, he thought, that relatives and friends should know that a certificate might be given in any particular case, though he did not make a practice of inquiring of the relieving officer if there were relatives, and why they were not present. He was of the opinion that it would be well to have a second certificate in pauper as well as in private cases.

Answering a question with regard to treatment, the witness said that in a large number of cases the proceedings and treatment were often too long delayed. He was under the impression that treatment prior to the stage at which certification could take place might prove to be remedial.

Sir Robert Walden, magistrate for the County of London, and chairman of the visiting magistrates for the county, agreed that personal contact was a great advantage, though it did not exist when private patients were admitted. He had had occasion to differ from medical men and had refused to sign certificates in certain cases, referring them back for further observation. He knew he had the right to call in another medical practitioner to inquire into such cases, but if they were difficult he would rather have the advice of an expert. With regard to provisional or experimental treatment, Sir Robert Walden was in favour of the establishment of a hostel under the management of an expert neurologist, assisted by trained nurses having psychological and other certificates, who should be able from time to time to report on the case. To such a home suspected cases could be sent before a certificate was issued, and he thought that since there would be no connexion with the workhouse or asylum, there might in many instances be a better chance of recovery. There might be two such institutions, one north and the other south of the Thames.

The Chairman said that at the end of the period of trial it might be found that certain patients were obviously cases for certification, and they would then pass to the asylum or to the workhouse, or possibly be the subject of application for reception to a licensed house. On the other hand, it might be found that as a result of the trial a person was not certifiable and ought to be returned to his or her friends. Could it not be hoped that during the period of provisional detention the cases benefiting by the quiet and treatment might completely recover?

Sir Robert Walden thought that 50 per cent. of the cases might do so. The provision of such institutions would relieve the pressure on the asylums in the metropolitan area, the accommodation in which had been inadequate for some time. From experience gained in the course of frequent personal visits to London asylums he had found, in conversing with patients, that in some instances there was justification for their complaints. Frequently, however, the complaints were not substantiated.

The Chairman asked whether Sir Robert Walden had any views in regard to some independent tribunal or investigation as to the state of a patient in an asylum.

Sir Robert Walden replied that in a border-line case it might be desired to consult an expert.

The Chairman asked if the witness thought it desirable that those dealing as medical practitioners with mental cases should have some special qualification as distinct from the qualifications of the ordinary medical practitioner. Sir Robert Walden replied that over and above general medical education, such practitioners should be specialists in that particular branch of work and have had considerable experience.

Sir Humphry Rolleston said he had been much impressed by the stress laid on the desirability of the judicial authorities being highly experienced men and the medical men specialists. Was the witness of the opinion that the judicial authorities should be as specialised in regard to the inquiry into diseases of the mind as the coroner in regard to investigation as to the cause of death?

Sir Robert Walden said it would be better, but he thought it was impossible. It would be necessary to have a paid authority. As to the medical man being as great a specialist as the coroner and pathologist, he maintained that a man dealing with mental cases could not have too much knowledge. Certainly the D.P.M. certificate should be held by all who dealt with such cases.

Earl Russell asked the witness if he thought it desirable that there should be instituted in England the practice prevalent in Scotland of boarding out suitable cases in villages. The witness replied that provided both the cases and the foster-parents were carefully selected, that might prove a desirable course in certain instances.

Councillor C. F. Sanders, magistrate for the city of Cardiff, said he had no difficulty in regard to certifying cases. He was, of course, bound to rely on the certificate of the medical officers. He did not understand it to be his task to examine a patient and satisfy himself from his own observation as to whether that patient was sane or insane. Continuing, the witness said that in the course of the past two years as many as 333 cases had passed through his hands, out of which number 58 had been discharged without a certificate having been granted. In answer to a question by the Chairman as to these 58 cases, Councillor Sanders replied that they were dropped for various reasons, a large proportion of the cases having been brought in suffering from delirium tremens and the taking of methylated spirits, whilst others apparently suffered from severe depression of sudden onset, which after a short rest had passed off. There was sufficient accommodation in Cardiff for all cases arising in the area. Councillor Sanders had never seen anything to suggest to him that any further precautions to protect the public against undue detention were required.

The evidence elicited during the sitting showed that there were differences of procedure as between Birmingham and Cardiff. Whilst Councillor Sanders said that in 19 cases out of 20 he had before him, when considering the signing of certificates of detention, written statements from relatives or friends as to what they knew of the alleged lunatics, Mr. Lord said he made no inquiry as to whether the patient had either relatives or friends. Again, in Birmingham the workhouse was not used as an original place of detention or as a place in which the justice might visit the patient, whereas in Cardiff it was the almost invariable practice to use the workhouse for both purposes.

The Commission adjourned until Nov. 4th.

Reviews and Notices of Books.

THE EXTRA PHARMACOPŒIA.

Eighteenth edition. In two volumes. Volume I. Revised by W. HARRISON MARTINDALE, Ph.D., F.C.S., and W. WYNN WESTCOTT, M.D. Lond., D.P.H. Lond. London: H. K. Lewis and Co., Ltd. 1924. Pp. 1163+xxxviii. 27*s.* 6*d.*

IN the four years since the last edition of the Extra Pharmacopœia appeared much work has been done on the chemical and physical properties of the substances used in medicine, research to which the authors have made their own contribution. All this practical laboratory work has been summarised and critically sifted with a view to presenting to the practitioner and pharmacist a key to up-to-date information on drugs and therapeutic agents in a pithy and concise form. Some new features appear in the present edition. Notes on alkaloids deal with both bench work and physiological trial, and a means is suggested of enhancing the effect of these drugs by the simultaneous use of alkali; this "activation" is corroborated by experiment on the authors and their assistants. Information on periodides, unavailable elsewhere, is given in this book along with the actual therapeutic doses determined by use in man. Attention is called to the intravenous application of salts of aspirin, the calcium salt having proved of definite service in relieving pain in sciatic and rheumatic affections. A heroic attempt has been made to bring the evidence regarding alkali bismuth tartrates into proper order. The provisions of the Dangerous Drugs Acts are set out in a form which makes the duties both of medical man and pharmacist clear at sight. Timely information will be found on many current topics; the value of ethanesal, the properties of nucleinic acid in increasing the leucocyte count, the fact that solutions of cocaine hydrochloride really can be boiled in glass vessels, the claims of Besredka to produce vaccines effective on oral administration. The poisons schedule is brought up to date, and an intravenous dose table throws light on dosage in a field where standardisation has been imperfect. Not the least interesting part of the book is the preface containing some remarks straight from the heart of a dispensing chemist who would welcome the confidence of the physician on matters of doubt relating to prescriptions. The authors appeal to the practitioner to help forward the British drug industry.

We have said enough to show that in its new form the Extra Pharmacopœia remains a storehouse of current information and a safe book of reference. We repeat our opinion that it is one of the few books which the medical practitioner, the analyst, and the pharmacist cannot afford to be without.

FERTILITY AND STERILITY IN HUMAN MARRIAGES.

By EDWARD REYNOLDS, M.D., and DONALD MACOMBER, M.D. London and Philadelphia: W. B. Saunders Company. 1924. Illustrated. Pp. 285. 25*s.*

THIS is a comprehensive monograph on a subject that has received considerable attention in the last 20 years. From the beginning the authors emphasise the fact that modern research has shown more and more emphatically the importance of the male in all questions of fertility, and for this reason they have secured the collaboration of an expert on the subject of male sterility, Dr. Edward L. Young, jun. Even such conditions as habitual miscarriage and one-child sterility are, as they point out, not necessarily indicative of trouble in the female. Miscarriage may be due to decreased fertility of either partner, the miscarriage resulting from the death of the fœtus or from its imperfect attachment to the uterus. Observations on animals have shown that in the cases of impaired fertility the uterus contains a percentage of blighted embryos interspersed among normal ones, the condition being due to conjugation by imperfect gametes. In an interesting chapter dealing with relative infertility in human marriages, the authors discuss the influence of diet, habit, physical exercise, nervous overstrain, and minor constitutional derangements on fertility. They quote instances of oligospermia in the human male which have been remedied by the adoption of a suitable diet and of sufficient outdoor exercise to improve assimilation, and it is obvious that if such changes can be effected in the male equally satisfactory results may be expected in the case of the female. The diet which is most favourable to fertility is one which contains a high percentage of animal proteins, together with some slight excess of vitamins and mineral salts. Associated with the alterations in diet should be a complete and prolonged change from habits of civilised life with the substitution of outdoor for indoor work. The alterations should, in the opinion of the authors, be made as early as possible in all cases in which marriage is not promptly followed by pregnancy. In the absence of voluntary prevention failure of prompt impregnation after marriage always implies at least some slight abnormality in the condition of one or other partner. In dealing with obviously diseased conditions of the genitalia it is interesting to note that the authors consider that the importance of gonorrhœa in causing female sterility has been exaggerated. This exaggeration they believe to have resulted from an unwarrantable assumption that chronic genital infections in a married woman, even unaccompanied by the history of an acute onset, are always due to unrecognised gonorrhœa in the husband. In actual fact non-specific infections are far more common than is usually recognised, and in the opinion of the authors these can be differentiated from gonococcal infections by the absence of a history of acute onset.

The book concludes with a chapter on the surgery of sterility. This includes operative measures on the cervix, such as Pozzi's operation, curettage, and the surgery of the ovaries and tubes. Included in the latter is a description of the technique of insufflation of the tubes with carbon dioxide gas as a means of diagnosis and treatment of tubular disease. Finally the authors point out that surgery, although it may be of use in remedying certain grosser defects, is only one of the weapons with which sterility can be attacked, and that in all cases it is of vital importance to consider carefully the physiology of the condition. It is indeed along physiological rather than pathological lines of study that future progress in this subject will be made.

This book is clearly written, well balanced in its views, and comprehensive in its outlook. We recommend it to all interested in this important subject, whether they be gynæcologists, genito-urinary surgeons, or general practitioners.

AMPUTATIONS.

By NORMAN THOMAS KIRK, M.D., F.A.C.S., Major, Medical Corps, U.S. Army. Published under the authority and with the approval of the Surgeon-General, U.S. Army. Washington, D.C.: *The Medical Interpreter.* 1924. Pp. 110+ix.

Major Kirk is chief of the Amputation and Orthopædic Section of the Walter Reid General Hospital at Washington, and here, as previously at No. 3 General Hospital in New Jersey, he has had exceptional experience of amputations, some 700 of which he has himself performed. He is therefore able to speak with authority. This monograph may, moreover, be considered as embodying the views officially approved by the medical authorities of the United States Army, seeing that Surgeon-General Ireland contributes a foreword to it. It must be a matter of congratulation that Major Kirk seems to have arrived at conclusions as to sites and methods of amputation very similar to those that were reached some years ago by British surgeons and expressed in works published in this country. The author describes an ingenious and apparently successful flap-sliding method for covering short guillotine stumps which is likely to be of use should the septic conditions of the war in France be repeated in the future, and which may well be borne in mind by all surgeons who have to amputate crushed limbs, with great destruction of soft parts, and consequent scarcity of covering for the bones. The provisional artificial leg adopted by the U.S. Army appears to be rather over-elaborate for its purpose, and to lack the simplicity of the fibre cone, deservedly popular in this country, which is not mentioned by Major Kirk. To many surgeons it appears better that the patient should have a provisional prosthesis as soon after amputation as possible, but this should be one as easily controlled as the jointless fibre cone, rather than an elaborate artificial limb with knee- and ankle-joints. Major Kirk describes and recommends a provisional arm made on somewhat similar lines to the leg.

Syphilis.

Kurzes Lehrbuch der Gesamten Syphilis mit besonderer Berücksichtigung der inneren Organe. Fachbücher für Ärzte, Band IX. Herausgegeben von E. Meirowsky, Köln, and Felix Pinkus, Berlin. Berlin: Julius Springer. Pp. 572. $6.50.

This is a complete handbook of syphilis edited by Drs. Meirowsky and Pinkus, in collaboration with 14 other writers. Prof. v. Wassermann contributes a concluding chapter.

The aim of the book is to bring the whole subject of syphilis in all its medical ramifications within one volume, and though we remain doubtful as to whether this is the best way to treat such a complicated subject, we must admit that much success has been achieved. The book has been kept within reasonable limits, and not much overlapping is found. The different chapters are each written by one who is an authority in his specialty. The change, however, in the style of writing from chapter to chapter makes the book less readable to the foreigner as a text-book, while as a work of reference it is too condensed. The chapters on syphilis of organs of the chest and abdomen and nervous system are excellent—that on syphilis of the organs of internal secretion is not so good. In the matter of therapy the notes are scrappy, excepting the part on the treatment of tabes.

The volume as a whole may be commended. It has been written and edited with the greatest care.

Infections by Unknown Organisms.

Traité de pathologie médicale et de thérapeutique appliquée. Vol. XVI., Infections à Germe Inconnu. Publié sous la direction de Emile Sergent, Professeur de Clinique Médicale Propédeutique, Médecin de la Charité, Membre de l'Académie de Médecine; L. Ribadeau-Dumas, Médecin de la Maternité; et L. Babonneix, Médecin de la Charité. Paris: A. Maloine et Fils. Pp. 143. Fr.25.

A collection of diseases due to infections by unknown organisms in a single volume is a good idea. Such a collection should give the reader a mass of information which is often difficult to sift from the usual sources, and it should, moreover, be a keen reminder of our ignorance of the essential pathology of many of the commonest diseases. The volume under review is, however, disappointing: many obscure infections are not mentioned, and there are included certain diseases, such as whooping-cough, in which the causal organism, if not finally and completely established, is nevertheless believed to be known, by the writers of the article amongst others. Apart from the paradox of its inclusion, the article on whooping-cough by E. Weill and Péhu is excellent, the clinical evidence that pertussis is infectious only in the stage before the paroxysmal cough develops being particularly interesting. H. Grenet's description of rheumatic fever is marred by the narrowness of his review of the world's literature; such English authorities as he quotes are often given with wrongly-spelt names, a fault which is deplorably common in French medical literature. British observers will not agree with this writer in his statement on page 267 that the essential lesions of rheumatic fever are in the joints. The most interesting articles in the volume are those by Prof. E. Marchoux, on sweating sickness, and by P. E. Armand-Delille, on influenza; the latter embraces a clear summary of our present knowledge, and may well be studied by all students to whom the late epidemic was an episode in their pre-medical days. Of the diseases omitted, trench fever and encephalitis lethargica are the most important; their absence is further evidence of what we have previously noted in this series—namely, a laxity in the general editing.

The Internal Secretions.

For the Use of Students and Physicians. By Dr. Arthur Weil, Assistant Professor of Physiology in the University of Halle. Authorised translation by Jacob Gutman, M.D., Director, Brooklyn Diagnostic Institute. London: George Allen and Unwin, Ltd. 1924. Pp. 287. 18s.
